## Supplementary Methods

## Genome Size Analysis by Flow Cytometry and Chromosome Counts

Flow cytometry (FC) was used for the determination of relative DNA amount. Fresh leaf material (ca. $0.5 \mathrm{~cm}^{2}$ ) of 202 L. sativum accessions, closely related L. spinescens and $L$. spinosum plus selected other Lepidium species (Supplemental Table 1 online) was chopped with a sharp razor blade into DAPI (4,6-diamino-2-phenylindole) solution and filtered into a sample tube. Subsequent FC analysis was performed on a Partec Ploidy Analyser-I (Partec) using an UV arc lamp. Diploid Lepidium campestre ( $2 \mathrm{n}=2 \mathrm{x}=16$ ) was used as an internal standard (FC value = 1.0). DAPI-stained mitotic chromosome metaphase spreads from $L$. sativum flower bud tissue were used for chromosome counts following the protocol of (1). The same methodology was used to prepare meiotic metaphase II spreads.

Seed Germination Assays. For germination analyses of A. thaliana and L. sativum FR14 seeds were placed onto $1 / 10$ Murashige-Skoog (MS) inorganic salts (Duchefa) solidified in $1 \%$ (w/v) agar-agar containing $0.1 \%$ plant preservative PPM (Plant Cell Technology) in Petri dishes and incubated in continuous white light (ca. $100 \mu \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ) in a Sanyo Versatile Environmental Test Chamber (MLR-350) at the temperatures indicated. All germination assays were carried out with 3 replicates of 50 seeds each. Testa and endosperm rupture were scored over time with a binocular microscope. Germination assays were partly carried out without (control) or with the following additions as indicated: $10 \mu \mathrm{M}$ cis-S(+)-ABA (Duchefa), $10 \mu \mathrm{M}$ gibberellin $\mathrm{A}_{4+7}\left(\mathrm{GA}_{4+7}\right.$; Duchefa), $10 \mu \mathrm{M}$ fluridone, $100 \mu \mathrm{M}$ paclobutrazol. Cold-stratification was carried out by placing the Petri dishes with the imbibed seeds for 3 days at $4^{\circ} \mathrm{C}$. Seed after-ripening was performed by storing fresh mature seeds at $25^{\circ} \mathrm{C}$ and $50 \%$ relative humidity for the time indicated.

## Plant Transformation

Plant transformation of $A$. thaliana dog1-1 (2) mutant plants was done by floral dip method, as described in (3) with the addition of $0.1 \%$ Silwet as a detergent. Briefly, Agrobacterium tumefaciens GV3101 harbouring the desired vector were grown for 2 days at $28^{\circ} \mathrm{C}$ in 500 ml YEB medium ( $5 \mathrm{~g} / \mathrm{l}$ beef extract, $1 \mathrm{~g} / \mathrm{l}$ yeast extract, $5 \mathrm{~g} / \mathrm{l}$ peptone, $5 \mathrm{~g} / \mathrm{l}$ sucrose, $0.5 \mathrm{~g} / \mathrm{l}$ $\mathrm{MgCl}_{2}, \mathrm{pH} 7.0$ ). The liquid culture was centrifuged for 20 min at 4000 rpm and the pellet was resuspended in $500 \mathrm{ml} 5 \%(\mathrm{w} / \mathrm{v})$ sucrose solution, containing $0.1 \%$ Silwet. Plants were held upside down into the bacterial solution for approximately 20 s , then the plants were incubated in plastic bags covered from light exposure overnight, then they were placed back into the greenhouse. Plant transformation was repeated twice. For L. sativum FR14 plant
transformation slightly differed since we experienced that the use of Silwet as detergent was harmful to L. sativum plants which led to strongly impaired seed formation. Therefore bacterial cultures were prepared basically as described as above but without the addition of Silwet. To compensate for the use of Silwet as a detergent vacuum infiltration was used as it has been shown to improve transformation efficiency (3). Lepidium sativum plants that just started opening the first flowers were selected for transformation. 9 plants were placed upside down into a custom made device and their flower buds dipped into the Agrobacterium solution and vacuum ( 150 mbar below ambient pressure) was applied to the plants for 5 min . Plants were incubated in plastic bags overnight covered from light exposure before placing them back into the greenhouse. Plants were transformed two times with approximately 10 days in between to allow plant recovery from vacuum treatment. T1 seeds were harvested, stratified on plates and germinated in cont. white light. Ungerminated seeds were treated with GA or scarified to ensure that also potentially dormant seeds produce seedlings which were then exposed to the subsequent selection procedure. Transgenic plants were identified by spraying BASTA on 7-d-old seedlings and repeating the spraying twice more after 4 d and 7 d. Homozygous lines were identified by BASTA selection in subsequent generations. Transgenic lines were propagated for at least 5 generations.

## Quantification of the Embryo Growth Potential

For the determination of the embryo growth potential (4) for every data point at least 20 seeds of $L$. sativum wild-type or Lesa-OxAtDOG1-E17 were imbibed in $1 / 10 \mathrm{MS}$ for 2 h , then the embryos were carefully extracted and transferred to clear microtiter plates containing 0 , 10, 15, 20, or 25 mM polyethylene glycol (PEG) 6000 (Carl Roth) in $1 / 10 \mathrm{MS}$ inorganic salts and incubated for 27 h at $24^{\circ} \mathrm{C}$ in continuous white light. For size determination of the radicle the embryos were transferred to a black ceramic plate during the incubation period after 1, 4, 7, 20, 23 and 27 h and photographed using a digital camera (Leica DFC480 with Leica IM1000 software) connected to a Leica MZ125 binocular stereo microscope with 20 -fold magnification. Twenty-four-bit RGB images at a resolution of $2560 \times 1920$ pixel (pixel aspect ratio=1) were saved in TIFF format. The image analysis was done as described in detail in (4) with the modification that in this work only the increase in radicle-hypocotyl axis size was determined as shown in Figure 5 in (4). Individual size increases were calculated relative to the size of each radicle-hypocotyl axis at the 1-h time point. For each sample a linear regression analysis of the size increase over time was performed to determine the growth rate per hour during the 27 h measuring interval. Osmolarity of the incubation medium was measured using a OM801 osmometer (Vogel). Osmotic pressure was calculated as described in (5).

## RNA Extraction and qRT-PCR Analysis (6)

For each replicate sample $L$. sativum seeds were imbibed at the temperatures and for the times indicated. 10 seeds for each replicate were harvested at the indicated physiological state and time, and either entire seeds or tissues were frozen in liquid nitrogen and subsequent RNA extraction and quality assessment was performed as described (6). RNA was reverse transcribed and qRT-PCR analysis and data normalisation was performed as described (6). Transcript abundance was normalized against the geometric mean of the three validated reference genes LesaG17210 (HQ912755), LesaG04660 (HQ912754) and LesaG20000 (HQ912757) for each sample. Primer sequences for selective amplification of the two LesaDOG1 paralogs in L. sativum: LesaDOG1A: LsDOG1AqPCR-F4 (5'-CTTTGTGTGGCTCCGAAACT-3') and LsDOG1AqPCR-R5 (5'-TTTTGGTCATCTTCTCTTCGTCTTCT-3'), these primers were also used for detecting LesaDOG1A overexpression in transgenic A. thaliana dog1-1 seeds by semiquantitative PCR; LesaDOG1B: LsDOG1BqPCR-F4 (5'-CTTTGTGTGGCTCTCAAACT-3') and LsDOG1BqPCR-R5 ( 5 '-TCTTGGTCATTTTCTCTTCCTCTTCT-3'). Primers for detecting L. sativum GID1A, GID1B, GID1C, EXLA1, EXPA9, XTH19 have been described in (7). Detection of the overexpressed AtDOG1 transgene in L. sativum seeds was performed using general A. thaliana DOG1 qPCR primers described in (8).
The qRT-PCR primers for transcript detection of genes for which no $L$. sativum sequence was available were designed to match the consensus sequence of 4 closely related Brassicaceae species (Arabidopsis thaliana, Capsella rubella, Brassica rapa and Thellungiella halophila) of the respective gene orthologs as determined by the Phytozome database (9) and validated by multiple sequence alignment and phylogenetic analysis. Primer for detecting EXPA2: Expa2-F (5'-CAGCCAAGGCTATGGGCTAC-3') and Expa2-R (5'-GCTCACAACAGTCCGACCAT-3'); KO: KO-FP1 (5'-ACATGGATAAGAAGCGTTGGGAG$\left.3^{\prime}\right)$ and KO-RP1 (5'-GCACCAGCACAAACCCTCT-3'); KAO1: KAO1-FP3 (5'-CTTGGGGAGAACAGGCACTATC-3') and KAO1-RP3 (5'-GCCAATGAAAGGCCAACCCA3'); KAO2: KAO2-FP4 (5'-GTCCGGTGATGTTCTTGCCT-3') and KAO2-RP4 (5'-GGCGTCGTTTTGGTGATTCTT-3'); GA20ox: GA20ox-gnrl-FP3 (5'-GGTGGTGAACAGCGAGAG-3') and GA20ox-gnrl-RP3 (5'-CGAGAGTGTTCATGTCTGCT3'); GA30x1: GA3ox1-FP4 (5'-GACATCGTTGAAGAGTACGAGGAA-3') and GA3ox1-RP4 (5'-AGGAGGGTGGAGTCGGTATG-3'). All resulting qRT-PCR amplicons were investigated for specificity by melt-curve analysis and correct amplicon size was determined by gel electrophoresis.

GA and ABA Metabolite Quantification. Seeds of L. sativum FR14 and Lesa-OxAtDOG1 lines imbibed at the temperatures and for the times indicated were sampled (17 seeds without testa rupture per replicate), frozen and ground in liquid nitrogen and freeze-dried. This resulted in approximately 30 mg whole seed powder per sample which was used for the quantitation of GA (5 replicates) and ABA (3-4 replicates) metabolites as described (4, 10).

## Supplementary Figures

Figure S1

Figure S1. Flow cytometry (FC) analysis to quantify relative genome sizes of Lepidium spp. accessions (see Supplemental Table 1 online). Presented are relative DNA amounts (FC values) of $L$. sativum, $L$. spinescens and $L$. spinosum accessions as well as reference species representing different chromosome numbers and ploidy levels. The diploid $L$. campestre ( $2 \mathrm{n}=2 \mathrm{x}=16$ ) was used as an internal standard ( $\mathrm{FC}=1.0$ ) and the relative FC values of $L$. sativum accessions varied between 2.71 and 2.85 ( $F C=2.77 \pm 0.08$, relative DNA amounts compared to L. campestre). Sample numbers are those of Supplemental Table 1 online which also contains the individual FC values and determined chromosome numbers. Based on these results $L$. sativum is a diploid species with $2 n=2 x=24$, a normal mitosis and meiosis, and a base chromosome number of $\mathrm{n}=12$.

Figure $\mathbf{S 2}$

B

Figure S2. Germination rate comparison of Lesa-OxAtDOG1 lines. [A] Transgenic Lepidium sativum lines (A2, A10, B13, E7, E17) harboring a chimeric transgene with the CaMV 35S-promoter driving an A. thaliana Cvi DOG1 genomic fragment (Lesa-OxAtDOG1) show a delayed germination phenotype. Shown are germination rates (GR) for testa and endosperm rupture (TR and ER). $N=3$, mean $\pm S E M$. Note that transgenic lines like Lesa-OxAtDOG1-D2 and GUS11 (a GUS reporter line used as transformation control), which did not accumulate the AtDOG1 protein (maintext Figure 4D) did also not show a delayedgermination phenotype, as evident by GR values similar to wild-type (WT). GRs were determined using the Germinator software (6). [B] Overexpression of AtDOG1 in L. sativum caused delayed germination which can be rescued by dormancy breaking treatments. Testa rupture germination rates (GRs) of WT and Lesa-OxAtDOG1-E17 at $24^{\circ} \mathrm{C}$ in continuous white light without (CON) or with dormancy breaking treatments: addition of $10 \mu \mathrm{M} \mathrm{GA}{ }_{4+7}$ (GA), seed dry after-ripening storage for 9 month (AR), addition of $10 \mu \mathrm{M}$ fluridone (FLU) and cold-stratification pre-treatment at $4^{\circ} \mathrm{C}$ in the dark for 3 days (STR). $N=3$, mean $\pm$ SEM. These TR GRs relate to the endosperm rupture GRs shown in the maintext in Figure 3A.

Figure S3

Figure S3. Initial resistance of embryo-encasing tissues of Lesa-OxAtDOG1-E17 and WT. The initial resistance of the combined embryo encasing tissues of the micropylar region (testa + endosperm) at $3-4 \mathrm{~h}$ of seed imbibition is not significantly different ( $p<0.05$ ) between Lepidium sativum WT and Lesa-OxAtDOG1-E17 as determined by puncture-force measurements. $\mathrm{N}=8$.

Figure S4

Figure S4. Temperature-dependent germination of Lesa-OxAtDOG1-E17 and WT in association with endosperm resistance and seed ABA levels.
[A] Germination rates for testa rupture at different imbibition temperatures of Lepidium sativum WT and transgenic Lesa-OxAtDOG1-E17 seeds overexpressing AtDOG1.
[B] L. sativum WT testa rupture (TR) and endosperm rupture (ER) at 18 and $24^{\circ} \mathrm{C}$.
[C] L. sativum transgenic Lesa-OxAtDOG1-E17 line TR and ER at 18 and $24^{\circ} \mathrm{C}$. Note that temperature has opposite effects on delaying germination in WT and E17 seeds. Panel B and C are shown for comparative reasons and this data is also presented in Figure 6B.
[D] Endosperm resistance of Lesa-OxAtDOG1-E17 seeds during germination at $18^{\circ} \mathrm{C}$ and $24^{\circ} \mathrm{C}$ in relation to seed ABA content. Puncture force measurements of the endosperm are shown (on the left axis) from seeds either with (+TR) or without (-TR) testa rupture. $N=20$, mean $\pm S E$. ABA levels (on the right axis) during germination at 18 and $24^{\circ} \mathrm{C}$ in E17 seeds with ( + TR) or without (-TR) testa rupture. $\mathrm{N}=3$, mean $\pm$ SE.

Figure S5

Figure S5. DOG1 controls the seed gibberellin metabolism in a temperature-dependent manner. Overexpression of AtDOG1 in seeds of Lepidium sativum leads to an increase of gibberellin (GA) metabolites and a strongly altered temperature regulation of GA metabolism during germination. Shown are GA metabolite contents of seed populations of L. sativum WT and Lesa-OxAtDOG1-E17 at different times during imbibition at $18^{\circ} \mathrm{C}$ and $24^{\circ} \mathrm{C}$. Samples from WT seeds were taken at $0,3,7$ and 11 h which corresponds to $0,10,50$ and $90 \%$ TR at $24^{\circ} \mathrm{C}$ (temperature optimum for WT) and $0,0,10$ and $50 \%$ TR at $18^{\circ} \mathrm{C}$ respectively. For Lesa-OxAtDOG1-E17 samples were taken at $0,10,30$ and 400 h corresponding to $0,0,10$ and $50 \%$ TR at $24^{\circ} \mathrm{C}$ and $0,0,50$ and $100 \%$ TR at $18^{\circ} \mathrm{C}$ (temperature optimum for E17). All seeds were sampled before testa rupture. Note that no E17 seeds with unruptured testa could be sampled at 400 h at $18^{\circ} \mathrm{C}$ because the whole seed population already completed germination. Shown are all analysed metabolites of the 13-non-hydroxylated (left) and 13hydroxylated (right) pathway. GA biosynthetic enzymes catalysing resepctive steps are indicated. Results are presented as per amount dry weight. $N=5$, mean $\pm$ SEM. Note that this figure is an alternative presentation of information which is partly shown in Fig. 5B in the maintext. Besides presenting data of all 20 analysed GA metabolites, here GA content changes are visualised on a physical timescale rather than on a physiological timescale as in Fig. 5 in the maintext. For numeric values of GA metabolites see Table S2.

Figure S6

Figure $\mathbf{S 7}$

Figure S7. Overexpressed AtDOG1 transcript and protein in Lesa-OxAtDOG1-E17 seeds during germination is highly abundant and expression level is not appreciably altered by germination temperature or the physiological state of the seed, i.e. having testa rupture (+TR) or not (-TR) as shown by [A] qRT-PCR analysis, $\mathrm{N}=4$, mean $\pm$ SEM and [B] Western blot analysis.

Figure S8

Figure S8. Temperature-dependent expression of endogenous LesaDOG1A and LesaDOG1B during germination of $L$. sativum WT at $18^{\circ} \mathrm{C}$ and $24^{\circ} \mathrm{C}$. TR = testa rupture. Note that germination temperature differentially affects LesaDOG1A and LesaDOG1B transcript abundance as determined by qRT-PCR. Note further that TR decreases LesaDOG1A transcript abundance at both temperatures whereas temperature has opposing effects on LesaDOG1B transcript abundance when undergoing TR late during germination. $N=3 \pm$ SEM.

Figure S9

Figure S9. The temperature-dependent influence of DOG1 on the expression of gibberellin (GA) biosynthesis and GA receptor genes. QRT-PCR gene expression profiles of the GA biosynthesis gene KAO1 and the GA receptor genes LesaGID1A, LesaGID1B and LesaGID1C during seed germination of Lepidium sativum line E17 overexpressing AtDOG1 compared to wild-type (WT) at $18^{\circ} \mathrm{C}$ and $24^{\circ} \mathrm{C}$. Seeds without (-TR) or with (+TR) testa rupture were sampled at the indicated time points which relate to the TR kinetics indicated by the grey curves. $N=3$, mean $\pm$ SEM.

Supplemental Table 1: Origin, microscopically determined chromosome number (mitotic and meiotic chromosome spreads), quantified relative DNA amount (FC-value) compared to Lepidium campestre ( $\mathrm{FC}=1.0$ ) and assumed ploidy level (if $\mathrm{x}=8$ ) of Lepidium sativum, L. spinescens and $L$. spinosum accessions and reference species representing different chromosome numbers and ploidy levels.

## Supplemental Table 1: Continued

| Taxon | Sample | Accession ${ }^{\text {X }}$ | Origin | Chromosome number ( $2 \mathrm{n} / \mathrm{n}$ ) | FC-value (relative) $^{Y}$ | Ploidy level $(\text { if } x=8)^{z}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| L. campestre | 223 | KM 2082 | Germany | 16 / | 1.000 | 2x |
| L. campestre | 224 | KM 2083 | Germany | 16 / | 1.000 | 2 x |

${ }^{\mathrm{X}}$ KM refers to accession numbers of K . Mummenhoff, other numbers refer to the Brassicaceae seed collection of the University of Osnabrück (OSBU).
${ }^{Y}$ Flow cytometry was used for the determination of relative DNA amount (FC-value). Diploid L. campestre $(2 n=2 x=16)$ was used as an internal standard ( $\mathrm{FC}=1.0$ ).
${ }^{z}$ Ploidy level is based on $x=8$.

Table S2. DOG1 controls the seed gibberellin metabolism in a temperature-dependent manner. Shown are GA metabolite contents of seed populations of $L$. sativum WT and Lesa-OxAtDOG1-E17 at different times during imbibition at $18^{\circ} \mathrm{C}$ and $24^{\circ} \mathrm{C}$. Samples from WT seeds were taken at $0,3,7$ and 11 h which corresponds to $0,10,50$ and $90 \%$ TR at $24^{\circ} \mathrm{C}$ (temperature optimum for WT) and $0,0,10$ and $50 \%$ TR at $18^{\circ} \mathrm{C}$ respectively. For Lesa-OxAtDOG1-E17 samples were taken at $0,10,30$ and 400 h corresponding to $0,0,10$ and $50 \%$ TR at $24{ }^{\circ} \mathrm{C}$ and 0 , 0,50 and $100 \%$ TR at $18^{\circ} \mathrm{C}$ (temperature optimum for E17). All seeds were sampled before testa rupture. Results are presented as pg per mg dry weight. $N=5$, mean $\pm$ SEM. These numeric values relate to Figures $5 B$ and $5 S$ in the maintext and supplements.
