Non-Commutative Formulas and Frege Lower Bounds: a New Characterization of Propositional Proofs

Abstract

Does every Boolean tautology have a short propositional-calculus proof? Here, a propositional calculus (i.e. Frege) proof is a proof starting from a set of axioms and deriving new Boolean formulas using a set of fixed sound derivation rules. Establishing any super-polynomial size lower bound on Frege proofs (in terms of the size of the formula proved) is a major open problem in proof complexity, and among a handful of fundamental hardness questions in complexity theory by and large. Non-commutative arithmetic formulas, on the other hand, constitute a quite weak computational model, for which exponential-size lower bounds were shown already back in 1991 by Nisan [Nis91] who used a particularly transparent argument.

In this work we show that Frege lower bounds in fact follow from corresponding size lower bounds on non-commutative formulas computing certain polynomials (and that such lower bounds on non-commutative formulas must exist, unless ***NP=coNP***). More precisely, we demonstrate a natural association between tautologies T to non-commutative polynomials p, such that:

- if T has a polynomial-size Frege proof then p has a polynomial-size non-commutative arithmetic formula; and conversely, when T is a DNF, if p has a polynomial-size non-commutative arithmetic formula over $GF(2)$ then T has a Frege proof of quasi-polynomial size.

The argument is a characterization of Frege proofs as non-commutative formulas: we show that the Frege system is (quasi-) polynomially equivalent to a *non-commutative Ideal Proof System* (IPS), following the recent work of Grochow and Pitassi [FOCS 2014] that introduced a propositional proof system in which proofs are arithmetic circuits, and the work in [Tza11] that considered adding the commutator as an axiom in algebraic propositional proof systems. This gives a characterization of propositional Frege proofs in terms of (non-commutative) arithmetic formulas that is tighter than (the formula version of IPS) in Grochow and Pitassi [FOCS 2014], in the following sense:

(i) The non-commutative IPS is *polynomial-time checkable*—whereas the original IPS was checkable in probabilistic polynomial-time; and

(ii) Frege proofs *unconditionally* quasi-polynomially simulate the non-commutative IPS—whereas Frege was shown to efficiently simulate IPS only assuming that the decidability of PIT for (commutative) arithmetic formulas by polynomial-size circuits is efficiently provable in Frege.

1 Introduction

1.1 Propositional proof complexity

The field of propositional proof complexity aims to understand and analyze the computational resources required to prove propositional statements. The problems the field poses

to us are fundamental, difficult and go back to the work of Cook and Reckhow [CR79], who showed the immediate relevance of these problems to the ***NP*** vs. ***coNP*** problem (and thus the ***P*** vs. ***NP*** problem).

Among the major unsolved questions in proof complexity, is whether the standard propositional logic calculus, either in the form of the Sequent Calculus, or equivalently, in the axiomatic form of Hilbert proofs (i.e., Frege proofs), is polynomially bounded; that is, whether every propositional tautology (or unsatisfiable formula) has a proof whose size is polynomially bounded (refutation, resp.) in the size of the formula proved. Here, we consider the size of proofs as the number of symbols it takes to write them down, where each formula in the proof is written as a Boolean *formula* (in other words we count the total number of logical gates appearing in the proof where each proof-line is a formula). It is known [Rec76] that all Frege proof-systems[1] as well as the Gentzen sequent calculus (with the cut rule) are polynomially equivalent to each other, and hence it does not matter precisely which rules, axioms, and logical-connectives we use.

Complexity-wise, the Frege proof system is considered a very strong system alas a poorly understood one. The qualification *strong* here has several meanings: first, that no super-polynomial lower bound is known for Frege proofs. Second, that there are not even good hard candidates for the Frege system (see [BBP95, Kra11, LT13] for a further discussion on hard proof complexity candidates). Third, that for most hard instances (e.g., the pigeonhole principle and Tseitin tautologies) that are known to be had for weaker systems (e.g., resolution, cutting planes, etc.), there *are* known polynomial bounds on Frege proofs. Fourth, that proving super-polynomial lower bounds on Frege proofs seems to a certain extent out of reach of current techniques. And finally, that by the common (mainly informal) correspondence between circuits and proofs—namely, the correspondence between a circuit-class $\mathcal{C}$ and a proof system in which every proof-line is written as a circuit from $\mathcal{C}$[2]—Frege system corresponds to the circuit class of polynomial-size $\log(n)$-depth circuits denoted $\boldsymbol{NC}^1$ (equivalently, of polynomial-size formulas [Spi71]), considered to be a strong computational model for which no (explicit) super-polynomial lower bounds are currently known.

Accordingly, proving lower bounds on Frege proofs is considered an extremely hard task. In fact, the best lower bound known today is only quadratic [Kra95], which uses a fairly simple syntactic argument. If we put further impeding restrictions on Frege proofs, like restricting the depth of each formula appearing in a proof to a certain fixed constant, exponential lower bounds can be obtained [Ajt88, PBI93, PBI93]. Although these constant-depth Frege exponential-size lower bounds go back to Ajtai's result from 1988, they are still in some sense the state-of-the-art in proof complexity lower bounds (beyond the important developments on weaker proof systems, such as resolution and its weak extensions). Constant-depth Frege lower bounds use quite involved probabilistic arguments, mainly specialized switching lemmas tailored for specific tautologies (namely, counting tautologies, most notable of which are the Pigeonhole Principle tautologies). Even random k-CNF formulas near the satisfiability threshold are not known to be hard

[1] Formally, a Frege proof system is any propositional proof system with a fixed number of axiom schemes and derivation rules which is also implicationally complete in which proof-lines are written as propositional formulas (see e.g., [Kra95] and Definition 8).

[2] To be more precise, one has to associate a circuit class $\mathcal{C}$ with a proof system in which a *family* of proofs is written such that every proof-line in the family is a circuit family from $\mathcal{C}$.

for constant-depth Frege (let alone hard for [unrestricted depth] Frege).

All of the above goes to emphasize the importance, basic nature and difficulty in understanding the complexity of strong propositional proof systems, while showing how little is actually known about these systems.

1.2 Prominent directions for understanding propositional proofs

As we already mentioned, there is a guiding line in proof complexity which states a correspondence between the complexity of circuits and the complexity of proofs. This correspondence is mainly informal, but there are seemingly good indications showing it might be more than a superficial analogy. One of the most compelling evidence for this correspondence is that there is a precise formal correspondence between the first-order logical theories of bounded arithmetic (whose axioms state the existence of sets taken from a given complexity class $\mathcal{C}$; cf. [CN10]) to propositional proof systems (in which proof-lines are circuits from $\mathcal{C}$).

Another facet of the informal correspondence between circuit complexity and proof complexity is that circuit hardness can sometimes be used to obtain proof-complexity hardness. The most notable example of this are the lower bounds on constant depth Frege proofs mentioned above: constant depth Frege proofs can be viewed as propositional logic operating with $\mathbf{AC}^0$ circuits, and the known lower bounds on constant depth Frege proofs (cf. [Ajt88, KPW95, PBI93]) use techniques borrowed from $\mathbf{AC}^0$ circuits lower bounds. The success in moving from circuit hardness towards proof-complexity hardness has spurred a flow of attempts to obtain lower bounds on proof systems other than constant depth Frege. For example, Pudlák [Pud99] and Atserias et al. [AGP02] studied proofs based on monotone circuits, motivated by known exponential lower bounds on monotone circuits. Raz and Tzameret [RT08b, RT08a, Tza08] investigated algebraic proof systems operating with multilinear formulas, motivated by lower bounds on multilinear formulas for the determinant, permanent and other explicit polynomials [Raz09, Raz06]. Atserias et al. [AKV04], Krajíček [Kra08] and Segerlind [Seg07] have considered proofs operating with ordered binary decision diagrams (OBDDs), and the second author [Tza11] initiated the study of proofs operating with non-commutative formulas (see Sec. 1.5 for a comparison with the current work).

Until quite recently it was unknown whether the correspondence between proofs and circuits is two-sided, namely, whether proof complexity hardness (of concrete known proof systems) can imply any computational hardness. An initial example of such an implication from proof hardness to circuit hardness was given by Raz and Tzameret [RT08b]. They showed that a separation between algebraic proof systems operating with arithmetic circuits and multilinear arithmetic circuits, resp., for an explicit family of polynomials, implies a separation between arithmetic circuits and multilinear arithmetic circuits. In a recent significant development about the complexity of strong proof systems, Grochow and Pitassi [GP14] demonstrated a much stronger correspondence. They introduced a natural propositional proof system, called the *Ideal Proof System* (IPS for short), for which *any* super-polynomial size lower bound on IPS implies a corresponding size lower bound on arithmetic circuits, and formally, that the permanent does not have small arithmetic circuits. The IPS is defined as follows:

Definition 1 (Ideal Proof System (IPS) [GP14]). *Let $F_1(\overline{x}), \ldots, F_m(\overline{x})$ be a system of polynomials in the variables $x_1, \ldots, x_n$, where the polynomials $x_i^2 - x_i$, for all $1 \leq i \leq n$, are part of this system. An* IPS refutation (or certificate) *that the F_i's polynomials have no 0-1 solutions is a polynomial $C(\overline{x}, \overline{y})$ in the variables $x_1, \ldots, x_n$ and $y_1, \ldots, y_m$, such that:*

1. $F(x_1, \ldots, x_n, \overline{0}) = 0$*; and*
2. $F(x_1, \ldots, x_n, F_1(\overline{x}), \ldots, F_m(\overline{x})) = 1$.

The essence of IPS is that a proof (or refutation) is a *single* polynomial that can be written simply as an arithmetic *circuit* or *formula*. The advantage of this formulation is that now we can obtain direct connections between circuit/formula hardness (i.e., "computational hardness") and hardness of proofs. Grochow and Pitassi showed indeed that a lower bound on IPS written as an arithmetic circuit implies that the permanent does not have polynomial-size algebraic circuits (Valiant's $\mathsf{VNP} \neq \mathsf{VP}$ [Val79]); And similarly, a lower bound on IPS written as an arithmetic *formula* implies that the permanent does not have polynomial-size algebraic formulas (Valiant's $\mathsf{VNP} \neq \mathsf{VP}_\mathsf{e}$).

Under certain assumptions, Grochow and Pitassi [GP14] were able to connect their result to standard propositional calculus proof systems, i.e., Frege and Extended Frege. Their assumption was the following: *Frege has polynomial-size proofs of the statement expressing that the PIT for arithmetic formulas is decidable by polynomial-size Boolean circuits* (*PIT for arithmetic formulas* is the problem to decide whether an input arithmetic formula computes the (formal) zero polynomial). They showed that[3], under this assumption super-polynomial lower bounds on Frege proofs imply that the permanent does not have polynomial-size arithmetic circuits. This, in turn, can be considered as a (conditional) justification for the apparent difficulty in proving lower bounds on strong proof systems.

1.3 Overview of results and proofs

1.3.1 Sketch

In this paper we contribute to the understanding of strong proof systems such as Frege, and to the fundamental search for lower bounds on these systems, by formulating a very natural proof system—a non-commutative variant of the ideal proof system—which we show captures *unconditionally* (up to a quasipolynomial-size increase) propositional Frege proofs. A proof in the non-commutative IPS is simply a *single non-commutative polynomial* written as a non-commutative formula. This gives a fairly compelling and simple new characterization of the proof complexity of propositional Frege. Moreover, it brings new hope for achieving lower bounds on strong proof systems, by reducing the task of lower bounding Frege proofs to the following seemingly much more manageable task: proving matrix rank lower bounds on the matrices associated with certain non-commutative polynomials (in the sense of Nisan [Nis91]; see below for details).

[3]We focus only on the relevant results about Frege proofs from [GP14] (and not the results about Extended Frege; the latter proof system operates, essentially, with Boolean circuits, in the same way that Frege operates with Boolean formulas (equivalently $\boldsymbol{NC}^1$ circuits)).

We also tighten the results in Grochow and Pitassi [GP14], in the sense that we show that in order to obtain a characterization of Frege proof in terms of an ideal proof system it is advantageous to consider non-commutative polynomials instead of commutative ones (as well as to add the commutator axioms). This shows that, at least for Frege, and in the framework of the ideal proof system, lower bounds on Frege proofs do not necessarily entail in themselves very strong computational lower bounds.

1.3.2 Some preliminaries: non-commutative polynomials and formulas

A *non-commutative polynomial* over a given field $\mathbb{F}$ and with the variables $X := \{x_1, x_2, \ldots\}$ is a formal sum of monomials with coefficients from $\mathbb{F}$ such that the product of variables is non-commuting. For example, $x_1x_2 - x_2x_1 + x_3x_2x_3^2 - x_2x_3^3$, $x_1x_2 - x_2x_1$ and 0 are three distinct polynomials in $\mathbb{F}\langle X\rangle$. The ring of non-commutative polynomials with variables X with coefficients from $\mathbb{F}$ is denoted $\mathbb{F}\langle X\rangle$.

A *polynomial* (i.e., a *commutative* polynomial) over a field is defined in the same way as a non-commutative polynomial except that now the product of variables *is* commutative; that is, it is a sum of (commutative) monomials.

A *non-commutative arithmetic formula* (non-commutative formula for short; see Definition 9) is a fan-in two labeled tree, with edges directed from leaves towards the root, such that the leaves are labeled with field elements (for a given field $\mathbb{F}$) or variables $x_1, \ldots, x_n$, and internal nodes (including the root) are labeled with a plus $+$ or product $\times$ gates. A product gate has an order on its two children (holding the order of non-commutative product). A non-commutative formula computes a non-commutative polynomial in the natural way.

Exponential-size lower bounds on non-commutative formulas (over any field) were established by Nisan [Nis91]. The idea (in retrospect) is quite simple: first transform a non-commutative formula into an algebraic branching program (ABP; see Definition 19); and then show that the number of nodes in the ith layer of an ABP computing a degree d homogenous non-commutative polynomial f is bounded from below by the rank of the degree i-partial-derivative matrix of f.[4] Thus, lower bounds on non-commutative formulas follow from quite immediate rank arguments (e.g., the partial derivative matrices associated with the permanent and determinant can easily be shown to have high ranks).

1.3.3 Non-commutative Ideal Proof System

Recall the IPS refutation system in Definition 1 above. We use the idea introduced in [Tza11], that considered adding the commutator $x_1x_2 - x_2x_1$ as an axiom in propositional algebraic proof systems, to define a refutation system that polynomially simulates Frege:

Definition 2 (Non-commutative IPS)**.** *Let $\mathbb{F}$ be a field. Assume that $F_1(\overline{x}) = F_2(\overline{x}) = \cdots = F_m(\overline{x}) = 0$ is a system of non-commutative polynomial equations from $\mathbb{F}\langle x_1, \ldots, x_n\rangle$, and suppose that the following set of equations (axioms) are included in the $F_i(\overline{x})$'s:*

Boolean axioms: $x_i \cdot (1 - x_i)$, *for all* $1 \leq i \leq n$;

[4] The degree i partial derivative matrix of f is the matrix whose rows are all non-commutative monomials of degree i and columns are all non-commutative monomials of degree $d - i$, such that the entry in row M and column N is the coefficient of the d degree monomial $M \cdot N$ in f.

Commutator axioms: $x_i \cdot x_j - x_j \cdot x_i\,, \quad$ *for all* $1 \leq i < j \leq n\,.$

Suppose that the $F_i(\overline{x})$*'s have no common* 0-1 *solutions.*[5] *A* ***non-commutative IPS refutation*** *(or* certificate*) that the system of* $F_i(\overline{x})$*'s is unsatisfiable is a non-commutative polynomial* $\mathfrak{F}(\overline{x},\overline{y})$ *in the variables* $x_1,\ldots,x_n$ *and* $y_1,\ldots,y_m$ *(i.e.* $\mathfrak{F} \in \mathbb{F}\langle\overline{x},\overline{y}\rangle$*), such that:*

1. $\mathfrak{F}(x_1,\ldots,x_n,\overline{0}) = 0$*; and*
2. $\mathfrak{F}(x_1,\ldots,x_n,F_1(\overline{x}),\ldots,F_m(\overline{x})) = 1.$

We always assume that the non-commutative IPS refutation is written as a *non-commutative formula*. Hence the ***size*** of a non-commutative IPS refutation is the minimal size of a non-commutative formula computing the non-commutative IPS refutation.

The main result of this paper is that the non-commutative IPS (over either $\mathbb{Q}$ or $\mathbb{Z}_q$, for any prime q) polynomially simulates Frege; and conversely, Frege quasi-polynomially simulates the non-commutative IPS (over $GF(2)$). We explain the results in what follows.

For the purpose of the next theorem, we use a standard translation of propositional formulas T into non-commutative arithmetic formulas:

Definition 3. *Let* $\mathrm{tr}(x_i) := x_i$*, for variables* x_i*;* $\mathrm{tr}(\mathsf{false}) := 1$*;* $\mathrm{tr}(\mathsf{true}) := 0$*; and by induction on the size of the propositional formula:* $\mathrm{tr}(\neg T_1) := 1 - \mathrm{tr}(T_1)$*;* $\mathrm{tr}(T_1 \vee T_2) = \mathrm{tr}(T_1) \cdot \mathrm{tr}(T_2)$ *and finally* $\mathrm{tr}(T_1 \wedge T_2) = 1 - ((1 - \mathrm{tr}(T_1)) \cdot (1 - \mathrm{tr}(T_2)))$*.*

For a non-commutative *formula* f denote by $\widehat{f}$ the non-commutative *polynomial* computed by f. Thus, T is a propositional tautology (i.e., a Boolean formula that is satisfied by every assignment) iff $\widehat{\mathrm{tr}(T)} = 0$ for every 0-1 assignment to the underlying variables of the non-commutative polynomial.

Theorem 1. *Let* $\mathbb{F}$ *be either* $\mathbb{Q}$ *or* $\mathbb{Z}_q$*, for a prime* q*. The non-commutative IPS refutation system, when refutations are written as non-commutative formulas over* $\mathbb{F}$*, polynomially simulates the Frege system. More precisely, for every propositional tautology* T*, if* T *has a polynomial-size Frege proof then there is a non-commutative IPS certificate (over* $\mathbb{F}$*) of* $\mathrm{tr}(\neg T)$ *that has a polynomial non-commutative formula size.*

The proof of Theorem 1 proceeds as follows. To simulate Frege proofs we use an intermediate proof system $\mathcal{F}$-$\mathcal{PC}$ formulated by Grigoriev and Hirsch [GH03]. The $\mathcal{F}$-$\mathcal{PC}$ system (Definition 11) is akin to the polynomial calculus refutation system [CEI96], except that we operate in $\mathcal{F}$-$\mathcal{PC}$ with *arithmetic formulas* treated as syntactic terms, instead of writing polynomials throughout the proof as sum of monomials. We have the two rules of polynomial calculus: from a pair of previously derived polynomials f, g we can derive $af + bg$ for $a, b \in \mathbb{F}$, and from f we can derive $x_i \cdot f$, for any variable x_i. We also have local rewriting rules, that can operate on any *sub*-formula of an arithmetic formula appearing in the proof. These rewriting rules express simple operations on polynomials like commutativity of addition and product, associativity, distributivity, etc.

Grigoriev and Hirsch [GH03] showed that $\mathcal{F}$-$\mathcal{PC}$ polynomially simulates Frege proofs, and that for tree-like Frege proofs the polynomial simulation yields tree-like $\mathcal{F}$-$\mathcal{PC}$ proofs.

[5] One can check that the $F_i(\overline{x})$'s have no common 0-1 solutions in $\mathbb{F}$ iff they do not have a common 0-1 solution in every $\mathbb{F}$-algebra.

Since tree-like Frege is polynomially equivalent to Frege (because Frege proofs can always be balanced to depth which is logarithmic in their size; cf. [Kra95] for a proof), we have that tree-like $\mathcal{F}$-$\mathcal{PC}$ polynomially simulates (dag-like) Frege proofs.

To conclude Theorem 1 it therefore remains to prove that non-commutative IPS polynomially simulates tree-like $\mathcal{F}$-$\mathcal{PC}$ proofs. This can be proved by induction on the number of lines in the $\mathcal{F}$-$\mathcal{PC}$ proofs. The interesting case in the induction is the simulation of the commutativity rewrite-rule for products by the non-commutative IPS system, which is done using the commutator axioms.

Now, since we write refutations as non-commutative formulas we can use the polynomial-time deterministic Polynomial Identity Testing algorithm for non-commutative formulas, devised by Raz and Shpilka [RS05], to check in *deterministic* polynomial-time the correctness of non-commutative IPS refutations. Therefore, we obtain:

Corollary 2. *The non-commutative IPS is a sound and complete Cook-Reckhow refutation system. That is, it is a sound and complete refutation system for unsatisfiable propositional formulas in which refutations can be checked for correctness in deterministic polynomial-time.*

This should be contrasted with the original (commutative) IPS of [GP14], for which verification of refutations is done in *probabilistic* polynomial time (using the standard Schwartz-Zippel [Sch80, Zip79] PIT algorithm).

The major consequence of Theorem 1 is that to prove a super-polynomial Frege lower bound it is now sufficient to prove a super-polynomial lower bound on non-commutative formulas computing certain polynomials. Specifically, it is enough to prove that any non-commutative IPS certificate $\mathfrak{F}(\overline{x}, \overline{y})$ (which is simply a non-commutative polynomial) has a super-polynomial non-commutative formula size; and yet in another words, it suffices to show that any such $\mathfrak{F}$ must have a super-polynomial total rank according to the associated partial-derivatives matrices discussed before.

We now consider the *other direction*, namely, whether Frege can simulate the non-commutative IPS. We show that it does for CNFs (this is the case considered in [GP14]), over $GF(2)$, and with only a quasi-polynomial increase in size. For convenience, we use a slightly different translation of clauses to non-commutative formulas than Definition 3:

Definition 4. *Given a Boolean formula f we define the non-commutative formula translation $\mathrm{tr}'(f)$ as follows. Let $\mathrm{tr}'(x) := 1 - x$ and $\mathrm{tr}(\neg x) := x$, for x a variable. And let $\mathrm{tr}'(f_1 \vee \ldots \vee f_r) := \mathrm{tr}'(f_1) \cdots \mathrm{tr}'(f_r)$ (where the sequence of products stands for a tree of product gates with $\mathrm{tr}'(f_i)$ as leaves). Further, for a clause k_i in a CNF $\phi = k_1 \wedge k_2 \ldots \wedge k_m$, denote by Q_i^ϕ the non-commutative formula translation $\mathrm{tr}'(k_i)$ of k_i, where $i = 1, 2, \ldots, m$.*

Theorem 3. *For a CNF $\phi = k_1 \wedge \ldots \wedge k_m$ where $Q_1^\phi, \ldots, Q_m^\phi$ are the corresponding non-commutative formulas for the clauses, if there is a non-commutative IPS refutation of size s of $Q_1^\phi, \ldots, Q_m^\phi$ over $GF(2)$, then there is a Frege proof of size $s^{O(\log s)}$ of $\neg\phi$.*

The proof of Theorem 3 consists of several separate steps of independent interest. Essentially, the argument is a short Frege proof for a *reflection principle* for the non-commutative IPS system (a reflection principle for a given proof system P is a statement

that says that if a formula is provable in P than the formula is also true). The argument becomes rather complicated because we need to prove properties of the *evaluation procedure* of non-commutative formulas, within the restricted framework of propositional Frege proofs.

The *quasi-polynomial blowup* in Theorem 3 depends *solely* on the fact that the reflection principle for non-commutative IPS is efficiently provable (apparently) only when the non-commutative IPS certificate is written as a sum of *homogenous* non-commutative formulas, as we now explain. Note that it is not known whether any arithmetic formula can be turned into a (sum of) homogenous formulas with only a polynomial increase in size (in contrast to the standard efficient homogenization of arithmetic *circuits*). Recently Raz [Raz13] showed how to transform an arithmetic formula into (a sum of) homogenous formulas with only a quasi-polynomial increase in size. In Lemma 18 we show that:

1. The same construction in [Raz13] holds also for *non-commutative* formulas.
2. This construction for non-commutative formulas can be carried out efficiently inside Frege. That is, if F is a non-commutative formula of size s computing a homogenous non-commutative polynomial over $GF(2)$ and F' is a homogenous non-commutative formula computing the same polynomial with size $s^{O(\log s)}$ (existing by [Raz13]), then Frege admits an $s^{O(\log s)}$ size proof of $F \equiv F'$.

Before we homogenize the non-commutative formulas (according to Raz' construction [Raz13]) we need to *balance* them, so that their depth is logarithmic in their size. We inspect that the recent construction of Hrubeš and Wigderson [HW14], for balancing non-commutative formulas with division gates (incurring at most a polynomial increase in size) results in a *division-free* formula, when the *initial* non-commutative formula is division-free itself. Therefore, we can assume that the non-commutative IPS certificate is already balanced.

To prove Theorem 3 we thus start with a non-commutative IPS certificate π over $GF(2)$ of the polynomial translation of the CNF ϕ, written as a *balanced* non-commutative formula (over $GF(2)$). We then consider this non-commutative polynomial identity *over* $GF(2)$ *as a Boolean tautology* by replacing plus gates with XOR and product gates with AND. We convert this Boolean tautology to a homogenous representation (as described above, using a simulation of [Raz13]). Now, we have a Boolean tautology which we denote by π.

We wish to prove $\neg\phi$ in Frege, using the fact that π is a (massaged version of a) non-commutative IPS certificate. To this end we essentially construct an efficient Frege proof of the correctness of the Raz and Shpilka non-commutative formulas PIT algorithm [RS05]. The PIT algorithm in [RS05] uses some basic linear algebraic concepts that might complicate the proof in Frege. However, since we only need to show the *existence* of short Frege proofs for the PIT algorithm's correctness, we can supply *witnesses* to witness the desired linear algebraic objects needed in the proof (these witnesses will be a sequence of linear transformations).

Furthermore, to reason inside Frege directly about the algorithm of [RS05] is apparently impossible, since this algorithm first converts a non-commutative formula into an *algebraic branching program* (ABP); but apparently the evaluation of ABPs cannot be done with Boolean formulas (and accordingly Frege possibly cannot reason about the evaluation of ABPs). The reason for this apparent inability of Frege to reason about ABP's

evaluation is that an ABP is a "sequential" object (an evaluation of an ABP seems to follow from the source to sink, level by level), while Frege operates with formulas, which are "parallel" objects (evaluation of [balanced] formulas can be done in logarithmic time, in case we have enough [separate] processors to perform parallel sub-evaluations of the formula). To overcome this obstacle we show how to perform Raz and Shpilka's PIT algorithm *directly on non-commutative formulas*, without converting the formulas first into ABPs. This technical contribution takes a large part of the argument (Sec. 5.6). We are thus able to prove the following statement, which might be interesting by itself:

Lemma 4. *If a non-commutative* homogeneous *formula $F(\overline{x})$ over $GF(2)$ of size s is identically zero, then the corresponding Boolean formula $\neg F_{bool}(\overline{x})$ (where F_{bool} results by replacing $+$ with XOR and $\cdot$ with AND in $F(\overline{x})$) can be proved with a Frege proof of size at most $s^{O(1)}$.*

1.4 Significance and discussion

The propositional-calculus is one of the most natural and central notions in logic, and within proof complexity it has a dominant role as a strong proof system whose structure and complexity is poorly understood. In that respect, our characterization of Frege proofs (and thus propositional-calculus) simply as non-commutative polynomials whose non-commutative formula size corresponds (up to a quasi-polynomial factor) to the size of Frege proofs, should be considered a valuable contribution. Since non-commutative formulas constitute a weak model of computation that is quite well understood, and since the Frege system is considered a strong proof system, and it is not entirely out of the way that Frege—or at least its extension, Extended Frege—is polynomially bounded (i.e., admits polynomial-size proofs for every tautology), our results showing the correspondence between Frege proofs and non-commutative formulas are quite surprising.

This correspondence, between non-commutative formulas and proofs, also gives renewed hope for progress on the major fundamental lower bounds problems in proof complexity: it reduces the problem of proving lower bounds on Frege proofs to the problem of establishing rank lower bounds on matrices associated with non-commutative polynomials, where the non-commutative polynomials are given "semi-explicitly" (that is, they are given in terms of the properties of the non-commutative IPS (Definition 2)). It is already known that rank lower bounds yielding strong non-commutative formulas lower bounds are fairly simple (cf. [Nis91]). This then provides a quite compelling evidence that Frege lower bounds, although mostly considered out of reach of current techniques, might not be very far away. Furthermore, our result simplifies greatly the high level-lower bound approach laid out in [GP14]: the suggested lower bound approach in [GP14] proposed to move from (commutative) arithmetic circuits lower bounds towards proof complexity lower bounds; but for (commutative) arithmetic circuits there are no known explicit lower bounds, in contrast to non-commutative formulas which constitute a well understood circuit class: both explicit exponential lower bounds and a deterministic PIT algorithms are known for non-commutative formulas.

The new characterization of Frege proofs also sheds light on the correspondence between *circuits and proofs* in proof complexity: in the framework of the ideal proof system, a Frege proof can be seen from the computational perspective as a non-commutative formula.

We also tighten the results of [GP14]. Namely, by showing that already the non-commutative version of the IPS is sufficient to simulate Frege. As well as by showing *unconditional* efficient simulation of the non-commutative IPS by Frege.

While proving that Frege quasi-polynomially simulates the non-commutative IPS, we demonstrate new simulations of algebraic complexity constructions within proof complexity; these include the homogenization for formulas of Raz [Raz13] and the PIT algorithm for non-commutative formulas by Raz and Shpilka [RS05]. These proof complexity simulations adds to the known previous such simulations shown in Hrubeš and Tzameret [HT12] and might be interesting by themselves.

Lastly, this work emphasizes the importance and usefulness of non-commutative models of computation in proof complexity (see [Hru11, LT13] for more on this).

1.5 Comparison with previous work

As discussed before, our main characterization of Frege system is based on a non-commutative version of the IPS system from Grochow and Pitassi [GP14]. As described above, the non-commutative IPS gives a tighter characterization than the (commutative) IPS in [GP14]. Thus, our proof system is seemingly weaker than the original (formula version of) IPS, and hence apparently *closer to capture the Frege system*.

Proofs in the original (formula version of the) IPS are arithmetic formulas, and thus any super-polynomial lower bound on IPS refutations implies $\mathsf{VNP} \neq \mathsf{VP_e}$, or in other words, that the permanent does not have polynomial-size arithmetic formulas (Joshua Grochow [personal communication]). This gives a justification of the considerable hardness of proving IPS lower bounds. On the other hand, an exponential-size lower bound on our non-commutative IPS gives only a corresponding lower bound on non-commutative formulas, for which exponential-size lower bounds are already known [Nis91]. Since Frege is quasi-polynomially equivalent to the non-commutative IPS, this means that exponential-size lower bounds on Frege implies merely—at least in the context of the Ideal Proof System—corresponding lower bounds on non-commutative formulas, a result which is however already known. This implies again that there is no strong concrete justification to believe that Frege lower bounds are beyond current techniques.

The work in [Tza11] dealt with propositional proof systems over non-commutative formulas. The difference with the current work is that [Tza11] formulated all proof systems as variants of the polynomial calculus and hence the characterization of a proof system in terms of a *single* non-commutative polynomial is lacking from that work (as well as the consequences we obtained in the current work).

2 Preliminaries

2.1 Frege proof systems

Definition 5 (Boolean formula)**.** *Given a set of input variables $x_1, \ldots, x_n$, a* Boolean formula *on the inputs is a rooted tree of fan-in at most two, with edges directed from leaves to the root. Internal nodes are labeled with the Boolean gates $\vee, \wedge, \neg$, and the fan-in of $\vee, \wedge$ is two and the fan-in of $\neg$ is one. The leaves are labeled either with input variables or with $0, 1$ (identified with the truth values* false *and* true*, resp.). The entire formula*

computes the function computed by the gate at the root. Given a formula F, the ***size*** *of the formula is the number of Boolean gates in F.*

Informally, a Frege proof system is just a standard propositional proof system for proving propositional tautologies (one learns in a basic logic course), having axioms and deduction rules, where proof-lines are written as Boolean formulas. The *size* of a Frege proof is the number of symbols it takes to write down the proof.

The problem of demonstrating super-polynomial size lower bounds on propositional proofs (called also Frege proofs) asks whether there is a family $(F_n)_{n=1}^{\infty}$ of propositional tautological formulas for which there is no polynomial p such that the minimal Frege proof size of F_n is at most $p(|F_n|)$, for all $n \in \mathbb{Z}^+$ (where $|F_n|$ denotes the size of the formula F_n).

Definition 6 (Frege rule)**.** *A* Frege rule *is a sequence of propositional formulas $A_0(\overline{x}), \ldots, A_k(\overline{x})$, for $k \leq 0$, written as $\frac{A_1(\overline{x}),\ldots,A_k(\overline{x})}{A_0(\overline{x})}$. In case $k = 0$, the Frege rule is called an* axiom scheme*. A formula F_0 is said to be* derived by the rule *from $F_1, \ldots, F_k$ if $F_0, \ldots, F_k$ are all substitution instances of $A_1, \ldots, A_k$, for some assignment to the $\overline{x}$ variables (that is, there are formulas $B_1, \ldots, B_n$ such that $F_i = A_i(B_1/x_1, \ldots, B_n/x_n)$, for all $i = 0, \ldots, k$). The Frege rule is said to be* sound *if whenever an assignment satisfies the formulas in the upper side $A_1, \ldots, A_k$, then it also satisfies the formula in the lower side A_0.*

Definition 7 (Frege proof)**.** *Given a set of Frege rules, a* Frege proof *is a sequence of Boolean formulas such that every proof-line is either an axiom or was derived by one of the given Frege rules from previous proof-lines. If the sequence terminates with the Boolean formula A, then the proof is said to be a* proof *of A. The* ***size*** *of a Frege proof is the the total sizes of all the Boolean formulas in the proof.*

A proof system is said to be *implicationally complete* if for all set of formulas T, if T semantically implies F, then there is a proof of F using (possibly) axioms from T. A proof system is said to be sound if it admits proofs of only tautologies (when not using auxiliary axioms, like in the T above).

Definition 8 (Frege proof system)**.** *Given a propositional language and a set P of sound Frege rules, we say that P is a* Frege proof system *if P is implicationally complete.*

Note that a Frege proof is always sound since the Frege rules are assumed to be sound. We do not need to work with a specific Frege proof system, since a basic result in proof complexity states that every two Frege proof systems, even over different languages, are polynomially equivalent [Rec76].

2.2 Algebraic proof systems

In this section, we give the definitions the algebraic proof systems Polynomial Calculus over Formulas ($\mathcal{F}$-$\mathcal{PC}$) defined by Grigoriev and Hirsch [GH03]. We start with the definition of a non-commutative formula:

Definition 9 (Non-commutative formula)**.** *Let $\mathbb{F}$ be a field and $x_1, x_2, \ldots$ be variables. A* noncommutative arithmetic formula *(or* noncommutative formula *for short) is a labeled*

tree, with edges directed from the leaves to the root, and with fan-in at most two, such that there is an order on the edges coming into a node (the first edge is called the left *edge and the second one the* right *edge). Every leaf of the tree (namely, a node of fan-in zero) is labeled either with an input variable x_i or a field $\mathbb{F}$ element. Every other node of the tree is labeled either with $+$ or $\times$ (in the first case the node is a plus gate and in the second case a product gate). We assume that there is only one node of out-degree zero, called* the root*. A noncommutative formula* computes *a noncommutative polynomial in $\mathbb{F}\langle x_1, \ldots, x_n\rangle$ in the following way. A leaf computes the input variable or field element that labels it. A plus gate computes the sum of polynomials computed by its incoming nodes. A product gate computes the* noncommutative *product of the polynomials computed by its incoming nodes according to the order of the edges. (Subtraction is obtained using the constant -1.) The output of the formula is the polynomial computed by the root. The* depth *of a formula is the maximal length of a path from the root to the leaf. The* ***size*** *of a noncommutative formula f is the total number of nodes in its underlying tree, and is denoted $|f|$.*

The definition of (a commutative) arithmetic formula is almost identical:

Definition 10 (Arithmetic formula)**.** *An* arithmetic formula *is defined in a similar way to a noncommutative formula, except that we ignore the order of multiplication (that is, a product node does not have order on its children and there is no order on multiplication when defining the polynomial computed by a formula).*

Given a pair of non-commutative formulas F and G and a variable x_i, we denote by $F[G/x_i]$ the formula F in which every occurrence of x_i is substituted by the formula G.

Note that an arithmetic formula is a syntactic object. For example, x_1+x_2 and x_2+x_1 are different formulas because commutativity might not hold (even if commutativity holds, we will regard them as different formulas. And in the proof system $\mathcal{F}$-$\mathcal{PC}$ they can be *derived* from each other via the "commutativity of addition").

2.2.1 $\mathcal{F}$-$\mathcal{PC}$

The $\mathcal{F}$-$\mathcal{PC}$ proof system defined by Grigoriev and Hirsch [GH03] operates with arithmetic formulas (as purely syntactic terms).

Definition 11 ($\mathcal{F}$-$\mathcal{PC}$ [GH03])**.** *Fix a field $\mathbb{F}$. Let $F := \{f_1, \ldots, f_m\}$ be a collection of* formulas[6] *computing polynomials from $\mathbb{F}[x_1, \ldots, x_n]$. Let the set of axioms be the following formulas:*

Boolean axioms $\quad x_i \cdot (1 - x_i)\,, \qquad$ *for all* $1 \le i \le n\,.$

A sequence $\pi = (\Phi_1, \ldots, \Phi_\ell)$ of formulas computing polynomials from $\mathbb{F}[x_1, \ldots, x_n]$ is said to be an $\mathcal{F}$-$\mathcal{PC}$ proof of Φ_ℓ from F*, if for every $i \in [\ell]$ we have one of the following:*

1. *$\Phi_i = f_j$, for some $j \in [m]$;*
2. *Φ_i is a Boolean axiom;*

[6] Note here that we are talking about formulas (treated as syntactic terms), and *not* polynomials. Also notice that all formulas in $\mathcal{F}$-$\mathcal{PC}$ are (commutative) formulas computing (commutative) polynomials.

3. Φ_i *was deduced by one of the following inference rules from previous proof-lines* Φ_j, Φ_k *, for* $j, k < i$*:*

Product

$$\frac{\Phi}{x_r \cdot \Phi}\ , \qquad \text{for } r \in [n]\,.$$

Addition

$$\frac{\Phi \qquad \Theta}{a \cdot \Phi + b \cdot \Theta}\ , \qquad \text{for } a, b \in \mathbb{F}\,.$$

(Where $\Phi, x_r \cdot \Phi, \Theta, a \cdot \Phi, b \cdot \Theta$ *are* formulas *constructed as displayed; e.g.,* $x_r \cdot \Phi$ *is the formula with product gate at the root having the formulas* x_r *and* Φ *as children.)*[7]

4. Φ_i *was deduced from previous proof-line* Φ_j*, for* $j < i$*, by one of the following* rewriting rules *expressing the polynomial-ring axioms (where* f, g, h *range over all arithmetic formulas computing polynomials in* $\mathbb{F}[x_1, \ldots, x_n]$*):*

Zero rule $0 \cdot f \leftrightarrow 0$

Unit rule $1 \cdot f \leftrightarrow f$

Scalar rule $t \leftrightarrow \alpha$*, where* t *is a formula containing no variables (only field* $\mathbb{F}$ *elements) that computes the constant* $\alpha \in \mathbb{F}$*.*

Commutativity rules $f + g \leftrightarrow g + f\,, \qquad f \cdot g \leftrightarrow g \cdot f$

Associativity rule $f + (g + h) \leftrightarrow (f + g) + h\,, \qquad f \cdot (g \cdot h) \leftrightarrow (f \cdot g) \cdot h$

Distributivity rule $f \cdot (g + h) \leftrightarrow (f \cdot g) + (f \cdot h)$

(The semantics of an $\mathcal{F}$*-*$\mathcal{PC}$ *proof-line* p_i *is the polynomial equation* $p_i = 0$*.) An* $\mathcal{F}$*-*$\mathcal{PC}$ refutation of F *is a proof of the formula* 1 *from* F*. The* ***size*** *of an* $\mathcal{F}$*-*$\mathcal{PC}$ *proof* π *is defined as the total size of all formulas in* π *and is denoted by* $|\pi|$*.*

Definition 12 (Tree-like $\mathcal{F}$-$\mathcal{PC}$)**.** *A system* $\mathcal{F}$*-*$\mathcal{PC}$ *is a* tree-like $\mathcal{F}$*-*$\mathcal{PC}$ *if every derived arithmetic formula in the proof system is used only once (and if it is needed again, it must be derived once more).*

Translation of Boolean formulas into polynomial equations. The proof system $\mathcal{F}$-$\mathcal{PC}$ can be considered as a propositional proof system for Boolean tautologies (namely, Boolean formulas that are true under any assignment). Given a Boolean formula T in the propositional variables $x_1, \ldots, x_n$ we can transform T into a set of polynomial equations by encoding it into a set of arithmetic formulas where each clause in the CNF corresponds to an arithmetic formula by replacing $\wedge$ with $\times$, $\vee$ with $+$ and $\neg x$ with $1 - x$; and for each variable x_i, add $x_i^2 - x_i$ (called the *Boolean axioms*) to guarantee that every satisfying assignment to the variables is a 0-1 assignment. Then the given CNF is a tautology if and only if the set of arithmetic formulas have no common root.

[7] In [GH03] the product rule of $\mathcal{F}$-$\mathcal{PC}$ is defined so that one can derive $\Theta \cdot \Phi$ from Φ, where Θ is any formula, and not just a variable. However, the definition of $\mathcal{F}$-$\mathcal{PC}$ in [GH03] and our Definition 11 polynomially-simulate each other.

Definition 13 (Polynomially Simulation)**.** *Let $\mathcal{P}_1, \mathcal{P}_2$ be two proof systems for the same language L (in case the proof systems are for two different languages we fix a translation from one language to the other, as described above). We say that $\mathcal{P}_2$* polynomially simulates *$\mathcal{P}_1$ if given a $\mathcal{P}_1$ proof (or refutation) π of a F, then there exists a proof (respectively, refutation) of F in $\mathcal{P}_2$ of size polynomial in the size of π. In case $\mathcal{P}_2$ polynomially simulates $\mathcal{P}_1$ while $\mathcal{P}_1$ does not polynomially simulates $\mathcal{P}_2$ we say that $\mathcal{P}_2$ is* strictly stronger *than $\mathcal{P}_1$.*

In [GH03], it was shown that $\mathcal{F}$-$\mathcal{PC}$, as well as tree-like $\mathcal{F}$-$\mathcal{PC}$, polynomially simulate Frege. We repeat the argument for the convenience of the reader:

Theorem 5 ([GH03])**.** *Tree-like $\mathcal{F}$-$\mathcal{PC}$ polynomially simulates Frege.*

Proof. The following was shown in [GH03]:

> **Theorem** (Theorem 3, [GH03])**.** *The system $\mathcal{F}$-$\mathcal{PC}$ polynomially simulates the Frege system.*

Moreover, inspecting the proof of the above theorem, we can observe that tree-like Frege proofs are simulated by tree-like $\mathcal{F}$-$\mathcal{PC}$ proofs:

Lemma 6. *Tree-like $\mathcal{F}$-$\mathcal{PC}$ polynomially simulates tree-like Frege systems.*

But Krajíček showed that tree-like Frege and Frege are polynomially equivalent:

> **Theorem** ([Kra95])**.** *Tree-like Frege proofs polynomially simulate Frege proofs.*

Thus, by this theorem and by Lemma 2.2.1, tree-like $\mathcal{F}$-$\mathcal{PC}$ polynomially simulates the Frege system. □

3 The non-commutative ideal proof system

The non-commutative ideal proof system (non-commutative IPS for short) is an algebraic refutation system in which a refutation is a single non-commutative polynomial. In the next section we show that when the non-commutative IPS refutations are written as *non-commutative formulas* then the non-commutative IPS polynomially simulates tree-like $\mathcal{F}$-$\mathcal{PC}$, and hence polynomially simulates the Frege proof system (by [GH03]).

Definition 14 (Non-commutative IPS)**.** *Let $\mathbb{F}$ be a field. Assume that $F_1(\overline{x}) = F_2(\overline{x}) = \cdots = F_m(\overline{x}) = 0$ is a system of non-commutative polynomial equations from $\mathbb{F}\langle x_1, \ldots, x_n\rangle$, and suppose that the following set of equations (axioms) are included in the $F_i(\overline{x})$'s:*

Boolean axiom: $x_i \cdot (1 - x_i)\,, \quad$ *for all* $1 \leq i \leq n\,;$
Commutator axiom: $x_i \cdot x_j - x_j \cdot x_i\,, \quad$ *for all* $1 \leq i < j \leq n\,.$

Suppose that the $F_i(\overline{x})$'s have no common 0-1 *solutions.*[8] *A* non-commutative IPS refutation *(or* certificate*) that the system of $F_i(\overline{x})$'s is unsatisfiable is a* ***non-commutative polynomial*** $\mathfrak{F}(\overline{x},\overline{y})$ *in the variables $x_1,\ldots,x_n$ and $y_1,\ldots,y_m$ (i.e. $\mathfrak{F}\in\mathbb{F}\langle\overline{x},\overline{y}\rangle$), such that:*

1. $\mathfrak{F}(x_1,\ldots,x_n,\overline{0})=0$*; and*
2. $\mathfrak{F}(x_1,\ldots,x_n,F_1(\overline{x}),\ldots,F_m(\overline{x}))=1$.

In this paper we assume that the non-commutative IPS refutation is written as a *non-commutative formula*. Hence the ***size*** of a non-commutative IPS refutation is the minimal size of a non-commutative formula computing the non-commutative IPS refutation.

Comment:

1. The identities in items 1 and 2 in Definition 14 are *formal* identities of polynomials (i.e., in 1 the polynomial in the left hand side has a zero coefficient for every monomial, and in 2 the only nonzero monomial is the monomial 1).

2. In order to prove that a system of *commutative* polynomial equations $\{P_i=0\}$ (where each P_i is expressed as an arithmetic formula) has no common roots in non-commutative IPS, we write each P_i *as a non-commutative formula* (in some way; note that there is no unique way to do this).

3. When we write $P\cdot Q-Q\cdot P$ where P,Q are formulas (e.g., x_i and x_j, resp.), we mean $((P\cdot Q)+(-1\cdot(Q\cdot P)))$.

4 Non-commutative ideal proof system polynomially simulates Frege

Here we show that the non-commutative IPS polynomially simulates Frege.

Theorem 7 (restatement of Theorem 1)**.** *The non-commutative IPS refutation system, when refutations are written as non-commutative formulas, polynomially simulates Frege systems. More precisely, for every propositional tautology T, if T has a polynomial-size Frege proof then there is a non-commutative IPS certificate (with integer coefficients) of polynomial non-commutative formula size.*

Recall that Raz and Shpilka [RS05] gave a deterministic polynomial-time PIT algorithm for non-commutative formulas (over any field):

Theorem 8 (PIT for non-commutative formulas [RS05])**.** *There is a deterministic polynomial-time algorithm that decides whether a given noncommutative formula over a field $\mathbb{F}$ computes the zero polynomial* 0.[9]

[8] One can check that the $F_i(\overline{x})$'s have no common 0-1 solutions in $\mathbb{F}$ iff they do not have a common 0-1 solution in every $\mathbb{F}$-algebra.

[9] We assume here that the field $\mathbb{F}$ can be efficiently represented (e.g., the field of rationals).

Now, since we write refutations as non-commutative formulas we can use the theorem above to check in *deterministic* polynomial-time the correctness of non-commutative IPS refutations, obtaining:

Corollary 9 (restatement of Corollary 2)**.** *The non-commutative IPS is a sound and complete Cook-Reckhow refutation system. That is, it is a sound and complete refutation system for unsatisfiable propositional formulas in which refutations can be checked for correctness in deterministic polynomial-time.*

To prove Theorem 7, we will show in Section 4.1 that the non-commutative IPS polynomially-simulates tree-like $\mathcal{F}$-$\mathcal{PC}$ (Definition 11), which sufficed to complete the proof due to Theorem 5.

4.1 Non-commutative IPS polynomially simulates tree-like $\mathcal{F}$-$\mathcal{PC}$

For convenience, let $C_{i,j}$ denote the commutator axiom $x_i \cdot x_j - x_j \cdot x_i$, for $i, j \in [n], i \neq j$.

Theorem 10. *Non-commutative IPS polynomially simulates Tree-like $\mathcal{F}$-$\mathcal{PC}$ (Definition 11).*

Proof. Let $F_1, \ldots, F_m$ be arithmetic formulas over the variables $x_1, \ldots, x_n$. Note that an arithmetic formula is a syntactic term in which the children of gates are ordered. We thus can treat a (commutative) arithmetic formula as a *non-commutative* arithmetic formula by taking the *order* on the children of products gates to be the order of non-commutative multiplication.

Suppose $\mathcal{F}$-$\mathcal{PC}$ has a poly(n)-size tree-like refutation $\pi := (L_1, \ldots, L_k)$ of the F_i's (i.e., a proof of the polynomial 1 from $F_1, \ldots, F_m$), where each L_j is an arithmetic formula. We construct a corresponding non-commutative IPS refutation of the F_i's from this $\mathcal{F}$-$\mathcal{PC}$ tree-like refutation. Denote by $|\pi|$ the size of π. We have the following:

Lemma 11. *For each $i \in [k]$, there exists a non-commutative formula ϕ_i such that*

1. $\phi_i(\overline{x}, \overline{0}) = 0$*;*
2. $\phi_i(\overline{x}, F_t, C_{j,j'}) = L_i$*, where $t \in [m]$, $j, j' \in [n]$, $j < j'$,*[10]
3. $|\phi_i| \leq \left(\sum_{\ell \in A_i} |L_\ell|\right)^4$*, where $A_i \subset [k]$ refers to the indices of the $\mathcal{F}$-$\mathcal{PC}$ proof-lines involved in deriving L_i.*[11]

Note that if the lemma holds, then ϕ_k will be a non-commutative IPS proof because it has the property that $\phi_k(\overline{x}, \overline{0}) = 0$ and $\phi_k(\overline{x}, F_t, C_{j,j'}) = L_k = 1$, where $t \in [m], j, j' \in [n], j \neq j'$. And its size is bounded by $\left(\sum_{\ell \in A_k} |L_\ell|\right)^4 \leq \left(\sum_{\ell \in [k]} |L_\ell|\right)^4 \leq O(|\pi|^4)$. Thus, non-commutative IPS polynomially simulates tree-like $\mathcal{F}$-$\mathcal{PC}$.

[10] This is an abuse of notation meaning $\phi_i(\overline{x}, F_1, \ldots, F_m, C_{1,2}, C_{1,3} \ldots, C_{n-1,n})$. We use a similar abuse of notation in the sequel.

[11] For example, if L_i is derived by L_α and L_α is derived by L_β for some $\beta < \alpha < i \in [k]$, then we say that α, β are both involved for deriving L_i.

Proof. We construct ϕ_i by induction on the length k of the refutation π. That is, for i from 1 to k, we construct the non-commutative formula $\phi_i(\overline{x}, \overline{y})$ according to L_i, as follows:

Case 1: The L_i is the input axiom F_j for some $j \in [m]$.
Let $\phi_i := y_j$. Obviously, $\phi_i(\overline{x}, 0) = 0, \phi_i(\overline{x}, F_t, C_{\alpha,\beta}) = F_j = L_i$ and $|\phi_i| = 1 \leq |L_i|^4$.

Case 2: The L_i is derived from an inference rule from previous proof-lines $L_j, L_{j'}$, for $j, j' < i$. Then we divide this case into two parts.

Part (1): The L_i is derived from the addition rule $L_i = aL_j + bL_{j'}$. Put $\phi_i := a\phi_j + b\phi_{j'}$ where $a, b \in \mathbb{F}$. Thus, $\phi_i(\overline{x}, 0) = a\phi_j(\overline{x}, 0) + b\phi_{j'}(\overline{x}, 0) = 0$, $\phi_i(\overline{x}, F_t, C_{\alpha,\beta}) = aL_j + bL_{j'} = L_i$ and $|\phi_i| = |\phi_j| + |\phi_{j'}| + 3 \leq \left(\sum_{\ell \in A_j} |L_\ell|\right)^4 + \left(\sum_{\ell \in A_{j'}} |L_\ell|\right)^4 + 3 \leq \left(\sum_{\ell \in A_i} |L_\ell|\right)^4$ (where the right most inequality holds since π is a *tree-like* refutation and hence $A_j \cap A_{j'} = \emptyset$).

Part (2): The L_i is derived from the product rule $L_i = x_r \cdot L_{j'}$ for $r \in [n]$. Put $\phi_i := (x_r \cdot \phi_j)$. Then $\phi_i(\overline{x}, 0) = x_r \cdot \phi_j(\overline{x}, 0) = 0, \phi_i(\overline{x}, F_t, C_{\alpha,\beta}) = x_r \cdot L_j = L_i$ and $|\phi_i| = |\phi_j| + 2 \leq \left(\sum_{\ell \in A_j} |L_\ell|\right)^4 + 2 \leq \left(\sum_{\ell \in A_i} |L_\ell|\right)^4$.

Case 3: The L_i is derived from L_j by a rewriting rule excluding the commutative rule of multiplication. Let $\phi_i := \phi_j$. The non-commutative ϕ_i satisfies the properties claimed trivially since all the rewriting rules (excluding the commutative rule of multiplication) express the non-commutative polynomial-ring axioms, and thus cannot change the polynomial computed by a non-commutative formula. And $|\phi_i| = |\phi_j| \leq \left(\sum_{\ell \in A_i} |L_\ell|\right)^4$.

Case 4: The L_i is derived from L_j by a single application of the commutative rule of multiplication. Then by Lemma 12 below, we can construct a non-commutative formula ϕ_{L_i,L_j} such that $\phi_i := (\phi_j + \phi_{L_i,L_j})$ satisfies the desired properties (stated in Lemma 11). □

Lemma 12. *Let L_i, L_j be non-commutative formulas such that L_i can be derived from L_j via the commutative rule of multiplication. Then there is a non-commutative formula $\phi_{L_i,L_j}(\overline{x}, \overline{y})$ in variables $\{x_\ell, y_{\alpha,\beta},\ \ell \in [n], \alpha < \beta \in [n]\}$, such that:*

1. $\phi_{L_i,L_j}(\overline{x}, \overline{0}) = 0$;
2. $\phi_{L_i,L_j}(\overline{x}, C_{\alpha,\beta}) = L_i - L_j$;
3. $\left|\phi_{L_i,L_j}\right| \leq |L_i|^2 |L_j|^2$.

Proof. We define the non-commutative formula ϕ_{L_i,L_j} inductively as follows:

- If $L_i = (P \cdot Q)$, and $L_j = (Q \cdot P)$, then ϕ_{L_i,L_j} is defined to be the formula constructed in Lemma 13 below.

- If $L_i = (P \cdot Q)$, $L_j = (P' \cdot Q')$.

  Case 1. If $P = P'$, then let $\phi_{L_i,L_j} := (P \cdot \phi_{Q,Q'})$.

  Case 2. If $Q = Q'$, then let $\phi_{L_i,L_j} := (\phi_{P,P'} \cdot Q)$.

- If $L_i = (P + Q)$, $L_j = (P' + Q')$.

  Case 1. If $P = P'$, then let $\phi_{L_i,L_j} = \phi_{Q,Q'}$.

  Case 2. If $Q = Q'$, then let $\phi_{L_i,L_j} = \phi_{P,P'}$.

By induction, one could check the construction satisfies the desired properties. □

Lemma 13. *For any pair P, Q of two non-commutative formulas there exists a non-commutative formula F in variables $\{x_\ell, y_{i,j},\ \ell \in [n], i < j \in [n]\}$ such that:*

1. $F(\overline{x}, \overline{0}) = 0$;
2. $F(\overline{x}, C_{i,j}) = P \cdot Q - Q \cdot P$;
3. $|F| = |P|^2 |Q|^2$.

Proof. Let $s(P, Q)$ denote the smallest size of F satisfying the above properties. We will show that $s(P, Q) \leq |P|^2 \cdot |Q|^2$ by induction on $\max(|P|, |Q|)$.

Base case: $|P| = |Q| = 1$.

In this case both P and Q are constants or variables, thus $s(P, Q) = 1 \leq |P|^2 |Q|^2$.

In the following induction step, we consider the case that $|P| \geq |Q|$ (which is symmetric for the case $|P| < |Q|$).

Induction step: Assume that $|P| \geq |Q|$ (the case $|P| < |Q|$ is similar).

Induction step case 1, the root of P is addition.

Case 1: The root of P is addition.

Let $P = (P_1 + P_2)$. We have (after rearranging):

$$P \cdot Q - Q \cdot P = ((P_1 \cdot Q - Q \cdot P_1) + (P_2 \cdot Q - Q \cdot P_2))$$

By induction hypothesis, we have $s(P, Q) \leq s(P_1, Q) + 1 + s(P_2, Q) \leq |P_1|^2 |Q|^2 + 1 + |P_2|^2 |Q|^2 \leq (|P_1| + |P_2| + 1)^2 |Q|^2 = |P|^2 \cdot |Q|^2$.

Case 2: The root of P is a product gate.

Let $P = (P_1 \cdot P_2)$. By rearranging:

$$P \cdot Q - Q \cdot P = ((P_1 \cdot (P_2 \cdot Q - Q \cdot P_2)) + ((P_1 \cdot Q - Q \cdot P_1) \cdot P_2))$$

By induction hypothesis, we have $s(P, Q) = |P_1| + 1 + s(P_2, Q) + 1 + s(P_1, Q) + 1 + |P_2| \leq |P_1| + 1 + |P_2|^2 |Q|^2 + 1 + |P_1|^2 |Q|^2 + 1 + |P_2| \leq (|P_1| + |P_2| + 1)^2 |Q|^2 = |P|^2 \cdot |Q|^2$. □

5 Frege quasi-polynomially simulates non-commutative IPS

In this section we prove that the Frege system quasi-polynomially simulates the non-commutative IPS (over $GF(2)$). Together with Theorem 10 this concludes Theorem 14 and gives a new characterization (up to a quasi-polynomial increase in size) of propositional Frege proofs as non-commutative arithmetic formulas.

We use the notation in Section 1.3.3: for a clause k_i in a CNF $\phi = k_1 \wedge \ldots \wedge k_m$, we denote by Q_i^ϕ the non-commutative formula translation $\mathrm{tr}'(k_i)$ of the clause k_i (Definition 4). Thus, $\neg x$ is translated to x, x is translated to $1 - x$ and $f_1 \cdots f_r$ is translated to $\prod_i \mathrm{tr}'(f_i)$ (considered as a tree of product gates with $\mathrm{tr}'(f_i)$ as leaves), and where the formulas are over $GF(2)$ (meaning that $1 - x$ is in fact $1 + x$).

Theorem 14 (Main quasi-polynomial simulation)**.** *For a 3CNF $\phi = k_1 \wedge \ldots \wedge k_m$ where $Q_1^\phi, \ldots, Q_m^\phi$ are the corresponding polynomial equations for the clauses, if there is a non-commutative IPS refutation of size s of $Q_1^\phi, \ldots, Q_m^\phi$ over $GF(2)$, then there is a Frege proof of size $s^{O(\log s)}$ of $\neg\phi$.*

The rest of the paper is dedicated to proving Theorem 14.

5.1 Balancing non-commutative formulas

We show that a non-commutative formula of size s can be balanced to an equivalent formula of depth $O(\log s)$. Both the statement and its proof are similar to Proposition 4.1 in Hrubeš and Wigderson [HW14] (which in turn is similar to the proof for the commutative formula with division gates case in Brent [Bre74]) . Note that a formula of a logarithmic depth must have a polynomial-size. (Thus, in the sequel, without loss of generality we will assume the F is given already in a balanced form, namely has depth $O(\log s)$ and polynomial-size which for simplicity we denoted simply as s.)

Lemma 15. *Assume that a non-commutative polynomial p can be computed by a formula of size s. Then p can be computed by a formula of depth $O(\log s)$ (and hence of polynomial-size).*

Proof. The proof is almost identical to the proof of Proposition 4.1 in [HW14], which deals with rational functions and allows formulae with division gates. Thus, we only outline the argument in [HW14] and argue that if the given formula does not have division gates, then the new formula obtained by the balancing construction will not contain any division gate either.

We need the following notations:

Notation. *Let F be a non-commutative formula and let g be a gate in F. We denote by F_g the subformula of F with the root being g and by $F[z/g]$ the formula obtained by replacing F_g in F by the variable z. We denote by $\widehat{F}, \widehat{F_g}$ the non-commutative* polynomials *in $\mathbb{F}\langle \overline{X} \rangle$ computed by F and F_g, respectively.*

We simultaneously prove the following two statements by induction on s, concluding the lemma:

Inductive statement: *Let F be a non-commutative formula of size s then for sufficiently large s and suitable constants $c_1, c_2 > 0$, the following hold:*

(i) $\widehat{F}$ has a non-commutative formula of depth at most $c_1 \log s + 1$;

(ii) if z is a variable occurring at most once in F, then:

$$\widehat{F} = A \cdot z \cdot B + C,$$

where A, B, C are non-commutative polynomials that do not contain z, and each can be computed by a non-commutative formula of depth at most $c_2 \log s$.

Base case: $s = 1$. In this case there is one gate g connecting two variables or constants. (i) can be obtained immediately as it is already computed by a formula of depth $1 = \log s + 1$. As for (ii), note that in the base case, F is a formula with only one gate g. Assuming that z is a variable occurring only once in F, it is trivial to construct non-commutative formulas A, B, C so that $\widehat{F} = A \cdot z \cdot B + C$ for which the conditions in (ii) hold:

Case 1: if g is a plus gate connecting the variable z and a variable or constant $x \neq z$, then $\widehat{F} := 1 \cdot z \cdot 1 + x$.
Case 2: if g is a product gate connecting z, x (for $z \neq x$) sequentially, then $F_g = 1 \cdot z \cdot x + 0$.
Case 3: if g is a product gate connecting x, z (for $z \neq x$) sequentially, namely in the reverse order, then $F_g = x \cdot z \cdot 1 + 0$.

Induction step: (i) is obtained roughly as follows. Find a gate g in F such that both F_g and $F[z/g]$ are small (of size at most $2s/3$, and where z is a new variable that does not occur in F). Then, by applying induction hypothesis on $F[z/g]$, there exist formulas A, B, C of small depth such that $\widehat{F[z/g]} = A \cdot z \cdot B + C$. Thus, $\widehat{F} := A \cdot \widehat{F_g} \cdot B + C$.

To prove (ii), find an appropriate gate g on the path between z and the output of F (an *appropriate* g is a gate g such that $F[z_1/g]$ and F_g are both small (of size at most $2s/3$), where z_1 is a new variable introduced for substitution). Use the inductive assumptions to write:

$$\widehat{F}[z_1/g] = A_1 \cdot z_1 \cdot B_1 + C_1 \quad \text{and} \quad \widehat{F}_g = A_2 \cdot z \cdot B_2 + C_2$$

and compose these expressions to get the following :

$$\widehat{F} = A_1 \cdot (A_2 \cdot z \cdot B_2 + C_2) \cdot B_1 + C_1 = A' \cdot z \cdot B' + C',$$

where $A' = A_1 \cdot A_2$, $B' = B_2 \cdot B_1, C' = A_1 \cdot C_2 \cdot B_1 + C_1$.

It is obvious that the depths of A', B', C' are at most $c_2 \log(2s/3) + 2 \leq c_2 \log s$ when s is sufficiently large.

To finish the proof of (ii), all that we need to show is that A', B', C' do not contain the variable z. It is enough to prove that $A_1, B_1, C_1, A_2, B_2, C_2$ do not contain z. Notice that F_g contains z and z is a variable occurring at most once in F. Therefore $\widehat{F[z_1/g]}$ does not contain the variable z, which means that both A_1, B_1, C_1 do not contain z. Moreover, by induction hypothesis, we know that A_2, B_2, C_2 do not contain z. Therefore, we conclude that A', B', C' do not contain z and thereby the whole proof. □

5.2 The reflection principle

Here we show that the existence of a non-commutative IPS refutation of size s and depth $O(\log s)$, implies the existence of a Frege proof with size $s^{O(\log s)}$ of $\neg\phi$. This is done by proving a *reflection principle* for the non-commutative IPS system in Frege. As mentioned in the introduction, informally, a reflection principle for a given proof system P is a statement that says that if a formula is provable in P then the formula is also *true*. Thus, suppose we have a short Frege-proof of the reflection principle for P, having the form:

$$\text{“}([\pi] \text{ is a } P\text{-proof of } [T]) \longrightarrow T\text{”},$$

where $[T]$ and $[\pi]$ are some reasonable encodings of the tautology T and its P-proof π, respectively. Then, we can easily obtain a Frege proof of T assuming we have a P-proof of T.

Let F be a non-commutative formula over $GF(2)$. First, note that F is a non-commutative IPS proof of ϕ only if it has the following two properties:

$$F\left(\overline{x}, \overline{0}\right) = 0, \qquad F\left(\overline{x}, \overline{Q}^{\phi}(\overline{x})\right) = 1, \tag{1}$$

showing the unsatisfiability of $\overline{Q}^{\phi}(\overline{x}) = 0$, and hence showing $\neg\phi$ is a tautology. We can treat F as a Boolean formula, as follows:

Definition 15 (Booleanization F_{bool})**.** *Let $F(\overline{x})$ be a non-commutative formula over $GF(2)$ in the (algebraic) variables $\overline{x}$. We denote by $F_{bool}(\overline{p})$ the Boolean formula in the (propositional) variables $\overline{p}$ obtained by turning every plus gate and multiplication gate to $\oplus$ (i.e., XOR) and $\wedge$ gates, respectively, and turning the input variables $\overline{x}$ into the propositional variables $\overline{p}$. We sometimes write F and F_{bool} without explicitly mentioning the $\overline{x}$ and $\overline{p}$ variables.*

Note that for any 0-1 assignment, F and F_{bool} have the same value Therefore, by the properties in (1), we know:

$$\neg F_{bool}\left(\overline{p}, \overline{0}\right), \qquad F_{bool}\left(\overline{p}, \overline{Q}^{\phi}(\overline{p})\right) \tag{2}$$

are both tautologies.

We proceed to prove $\neg\phi$ based on 2 first, before we show there exists an $s^{O(\log s)}$ proof of 2.

Lemma 16. $\left(\left(\neg F_{bool}\left(\overline{p}, \overline{0}\right)\right) \wedge F_{bool}\left(\overline{p}, \overline{Q}^{\phi}(\overline{p})\right)\right) \rightarrow \neg\phi$ *can be proved with a polynomial-size Frege proof.*

Proof. We will prove by way of a contradiction that:

$$\phi, \qquad \neg F_{bool}\left(\overline{p}, \overline{0}\right), \qquad F_{bool}\left(\overline{p}, \overline{Q}^{\phi}(\overline{p})\right) \tag{3}$$

cannot be simultaneously satisfied. Assume otherwise and let the Boolean formula $\mathsf{Truth}([\phi], \overline{p})$ express the statement that the assignment $\overline{p}$ satisfies the formula ϕ, as defined below. In the following we always denote by $\overline{p}$ *actual* propositional variables occurring in a propositional formula (and not an encoding of an assignment).

Definition 16 (Section 4.3 in [GP14])**.**

$$\mathit{Truth}([\phi],\overline{p}) := \bigwedge_{i\in[m]} \mathit{Truth}([k_i],\overline{p}).$$

For a single 3-literal clause k_i, define $\mathit{Truth}([k],\overline{p})$ as follows. For an integer i, let $[i]$ denote the standard binary encoding of i. And $[k] = \overline{q}_1 s_1 \overline{q}_2 s_2 \overline{q}_3 s_3$ where each s_i is the sign bit and each $\overline{q}_i$ is a length-$[\log_2 n+1]$ string of variables corresponding to the encoding of the index of a variable.

$$\mathit{Truth}([k],\overline{p}) := \bigvee_{j\in[3]} \bigvee_{i\in[n]} \left(\neg\ \overline{q}_j = i \wedge (p_i \leftrightarrow s_j)\right).$$

As $\mathsf{Truth}([k],\overline{p})$ is syntactically identical to $k(\overline{p})$, it can be easily proved as follows:

$$\phi(\overline{p}) \rightarrow \mathsf{Truth}([\phi],\overline{p}), \tag{4}$$

We proceed to prove the following formulae:

- $$\mathsf{Truth}([k_i],\overline{p}) \rightarrow \neg Q^{\phi}_{i_{bool}}(\overline{p}),\ \forall i \in [m]. \tag{5}$$

  Note that $\neg Q^{\phi}_{i_{bool}}(\overline{p})$ and $\mathsf{Truth}([k_i],\overline{p})$ are of constant size. So (by completeness) all the formulae in (5) above can be proved with a Frege proof of constant-size.

- Using the fact that $\mathsf{Truth}([\phi],\overline{p}) = \bigwedge_{i\in[m]} \mathsf{Truth}([k_i],\overline{p})$ we can easily prove in Frege with a polynomial-size proof that for each $i \in [m]$,

  $$\mathsf{Truth}([\phi],\overline{p}) \rightarrow \neg Q^{\phi}_{i_{bool}}(\overline{p}). \tag{6}$$

- By assumption ϕ together with modus pones using 4 and 6, we have:

  $$\bigwedge_{i\in[m]} \neg Q^{\phi}_{i_{bool}}(\overline{p}). \tag{7}$$

- We show below how to prove the following by a way of contradiction:

  $$\neg F_{bool}\left(\overline{p},\overline{0}\right) \wedge \bigwedge_{i\in[m]} \neg Q^{\phi}_{i_{bool}}(\overline{p}) \rightarrow \neg F_{bool}\left(\overline{p},\overline{Q}^{\phi}(\overline{p})\right). \tag{8}$$

  If there is an assignment $\overline{a}$ that makes $F_{bool}\left(\overline{a},\overline{Q}^{\phi}(\overline{a})\right)$ false, while $\neg F_{bool}\left(\overline{a},\overline{0}\right)$, $\bigwedge_{i\in[m]} \neg\overline{Q}^{\phi}_i(\overline{a})$ are still true, then the assignment must make $\overline{Q}^{\phi}(\overline{a}) \neq \overline{0}$, which is a contradiction with the fact that $\bigwedge_{i\in[m]} \neg\overline{Q}^{\phi}_i(\overline{a})$ is still true. Therefore, there is no such assignment $\overline{a}$. That is, 8 holds.

- Using the assumptions that $\neg F_{bool}\left(\overline{p},\overline{0}\right)$ and 7 together with modus pones on (8), we get:

  $$\neg F_{bool}\left(\overline{p},\overline{Q}^{\phi}(\overline{p})\right),$$

  which is a contradiction to $F_{bool}\left(\overline{p},\overline{Q}^{\phi}(\overline{p})\right)$. Therefore, we finish our proof.

□

It remains to show a quasi-polynomial-size proof of (2).
We denote $\neg F_{bool}\left(\overline{p},\overline{0}\right)$ and $\neg\left(1\oplus F_{bool}\left(\overline{p},\overline{Q}^{\phi}(\overline{p})\right)\right)$ by

$$F'_{bool}(\overline{p}),\quad F''_{bool}(\overline{p}),\quad \text{respectively.} \tag{9}$$

Note that the substitutions of the constants 0 or the constant depth formulae Q^{ϕ}_{bool} in F can not increase the depth of F too much (i.e., can add at most a constant to the size of F). In other words, the depths of the formulae in (9) are still $O(\log s)$.

Proof of Theorem 14 (Main quasi-polynomial simulation). Using Lemma 17 that we shall prove below, we get that 9 can be proved in quasi-polynomial-size. And together with Lemma 16 above, this shows that $\neg\phi$ can be proved in quasi-polynomial-size, concluding the proof. □

5.3 Non-commutative formula identities have quasi-polynomial-size proofs

Recall that a (commutative or non-commutative) multivariate polynomial f is *homogeneous* if every monomial in f has the same total degree. For each $0\leq j\leq d$, denote by $f^{(j)}$ the homogenous part of degree j of f, that is, the sum of all monomials (together with their coefficient from the field) in f of total degree j. We say that a formula is *homogeneous* if each of its gates computes a *homogeneous* polynomial (see Definition 9 for the definition of a polynomial computed by a gate or a formula).

To complete the proof of Theorem 14 it remains to prove the following:

Lemma 17. *If a non-commutative formula $F(\overline{x})$ with 0-1 coefficients of size s and depth $O(\log s)$ is identically zero, then the corresponding Boolean formula $\neg F_{bool}(\overline{p})$ admits a Frege proof of size $s^{O(\log s)}$.*

Proof. The formula F is of size s which means that the maximum degree of a polynomial computed by F is at most $s+1$. Following Raz' work in [Raz13], we can split F into homogenous formulae $F^{(i)}$, $i=0,\ldots,s+1$. In Lemma 18, proved in the sequel, we show that Raz' homogenization construction can already be proved efficiently in Frege. In other words, we show that there exists an $s^{O(\log s)}$-size Frege proof of:

$$\bigoplus_{i=0}^{s+1} F^{(i)} \leftrightarrow F_{bool}. \tag{10}$$

By Lemma 19 proved in the sequel, for any *homogenous* formula H, $\neg H_{bool}$ admits a polynomial-size in the size of H Frege proof (recall that $\neg H_{bool}$ is a tautology whenever H is a non-commutative formula computing the zero polynomial over $GF(2)$). Thus, by Lemma 19, for every $F^{(i)}$, $i=0,\ldots,s+1$, there exists an $s^{O(\log s)}$-size Frege proof of $\neg F^{(i)}_{bool}$. That is, there exists an $s^{O(\log s)}$-size Frege proof of $\neg\left(\bigoplus_{i=0}^{s+1} F^{(i)}_{bool}\right)$. (Note that Lemma 19 gives proofs which have size polynomial in the size of $\neg F^{(i)}_{bool}$, and this latter size is $s^{O(\log s)}$). Together with tautology (10), we can derive $\neg F_{bool}$ in Frege. □

5.4 Homogenization of non-commutative formulas has short Frege proofs

To complete the proof of Theorem 17 it remains to prove Lemmas 18 and 19. Here we prove the former, namely that Raz' construction from [Raz13] (see below) is efficiently provable in Frege:

Lemma 18. *If F is a non-commutative formula of size s and depth $O(\log s)$ and $F^{(0)},\ldots,F^{(s)}$ are the homogenous formulae computing F's homogenous parts of degree from 0 to s, respectively, constructed according to [Raz13], then there exists an $s^{O(\log s)}$-size Frege proof of:*

$$\bigoplus_{i=0}^{s+1} F^{(i)} \leftrightarrow F_{bool}. \tag{11}$$

Proof. We first give a sketch of Raz' (commutative) formula homogenization construction from [Raz13]. This is a slightly more involved variant of the standard homogenization construction for circuits (cf. [Str73]).

Raz' formula homogenization construction. Given a (commutative) arithmetic formula F we wish to construct s (commutative) formulas computing the homogenous parts $F^{(i)}$, $i=0,\ldots,s$. Define the *product-depth* of a gate u, denoted u_{pd}, as the maximal number of product gates along a directed path from u to the output gate. Since the formula F is balanced, the depth is at most $O(\log s)$, namely the largest value of u_{pd} for any node u in F is $O(\log s)$.

Furthermore, for every integer r, denote by N_r the family of monotone non-increasing functions D^u from $\{0,1,\ldots,r\}$ to $\{0,1,\ldots,s\}$. Thus, the size of N_r is $\binom{r+s+1}{r+1}=\binom{r+s+1}{s}$ (the number of combinations with repetitions of $r+1$ elements from $s+1$ elements, which determine functions in N_r). Thus, for every node u of F, the size of the set $N_{u_{pd}}$ is at most $\binom{s+O(\log s)+1}{s}=s^{O(\log s)}$.

We construct the desired homogenous formulae $F^{(0)},F^{(1)},\ldots,F^{(s+1)}$ by constructing a formula $F^\star$ according to F first. Split every gate u in F into $|N_{u_{pd}}|$ gates in $F^\star$, labeled (u,D^u), for every $D^u\in N_{u_{pd}}$ and add edges connecting nodes in the same way as [Raz13].

Denote by $F^\star_{u,D^u}$ the sub-formula rooted at (u,D^u) in $F^\star$ (there may be some isolated nodes (u,D^u), namely nodes that no edge connects with them, and we consider the sub-formulae on these nodes as 0). Similarly, denote by F_u the sub-formula rooted at u in F. In [Raz13] it was proved that for every node (u,D^u) in $F^\star$, $F^\star_{u,D^u}$ is a homogenous formula computing the homogenous part of degree $D^u(u_{pd})$ of F_u. More precisely, for every node u in F, denote by s_u the size of the formula F_u. The maximum degree of the polynomial computed by F_u is s_u+1. Furthermore, for $i=0,1,\ldots,s_u+1$, let $\mathcal{D}^u_i$ denote the set of functions D^u in $N_{u_{pd}}$ such that $D^u(u_{pd})=i$. The formulae $F^\star_{u,D^u}$, for $D^u\in\mathcal{D}^u_i$, are the formulae computing the homogenous parts of degree i of F_u. For simplicity, let $F^\star_{u,\mathcal{D}^u_i}$ denote such a formula.

Efficient proofs of the homogenization construction. Next, we use a similar induction argument as in [Raz13], from leaves to the top gate of F, showing that for every

gate u in F there exists an $s^{O(\log s)}$-size Frege proof of:

$$\bigoplus_{i=0}^{s_u+1} F^{\star}_{u,\mathcal{D}^u_i\ bool} \leftrightarrow F_{u\ bool}.$$

Observe that the formulae $F^{\star}_{r,\mathcal{D}^r_0}, \ldots, F^{\star}_{r,\mathcal{D}^r_{s+1}}$, computing the homogenous parts of all degree of the sub-formula rooted on the root of F, are just those desired formulae $F^{(0)}, F^{(1)}, \ldots, F^{(s+1)}$. Thus, eventually, when we prove the above statement for the root node r, we prove the existence of an $s^{O(\log s)}$-size Frege proof of the Boolean formulae in 11.

- If u is a leaf, by the construction, for each $D^u \in N_{u_{pd}}$, the node (u, D^u) is the leaf of $F^{\star}$. Furthermore, if u is labeled by a field element, (u, D^u) is labeled by the same field element if $D^u(u_{pd}) = 0$ and by 0 if $D^u(u_{pd}) \neq 0$. If u is labeled by an input variable, (u, D^u) is labeled by the same input variable if $D^u(u_{pd}) = 1$ and by 0 if $D^u(u_{pd}) \neq 1$. Thus, we know for each $D^u \in N_{u_{pd}}$, $F^{\star}_{(u,D^u)}$ either computes $F_u^{\left(D^u(u_{pd})\right)}$ or 0. Namely, we can easily prove the induction base:

$$\bigoplus_{i=0}^{s_u+1} F^{\star}_{bool\ u,\mathcal{D}^u_i} \leftrightarrow F_{bool\ u}.$$

- If u is a sum gate with children v, w, by construction, for every $D^u \in N_{u_{pd}}$, denote by $D^v \in N_{v_{pd}}$ the function that agrees with D^u on $\{0, 1, \ldots, u_{pd}\}$ and satisfies $D^v(v_{pd}) = D^u(u_{pd})$, and in the same way, denote by $D^w \in N_{w_{pd}}$ the function that agrees with D^u on $\{0, 1, \ldots, u_{pd}\}$ and satisfies $D^w(w_{pd}) = D^u(u_{pd})$. The node (u, D^u) computes:

  $$F^{\star}_{u,D^u} := F^{\star}_{v,D^v} + F^{\star}_{w,D^w}.$$

  Assume $D^u(u_{pd}) = j$. Then it means

  $$\hat{F}_{u,\mathcal{D}^u_j} := \hat{F}_{v,\mathcal{D}^v_j} + \hat{F}_{w,\mathcal{D}^w_j}.$$

  Therefore, the corresponding boolean formula of $\hat{F}_{u,\mathcal{D}^u_j}$ should have the following property:

  $$F^{\star}_{u,\mathcal{D}^u_j\ bool} \leftrightarrow F^{\star}_{v,\mathcal{D}^v_j\ bool} \oplus F^{\star}_{w,\mathcal{D}^w_j\ bool}, \quad j = 0, 1, \ldots, s.$$

  Together with the induction hypothesis on nodes v, w:

  $$F_{bool\ v} \leftrightarrow \bigoplus_{i=0}^{s_v+1} F^{\star}_{v,\mathcal{D}^v_i\ bool}, \quad F_{bool\ w} \leftrightarrow \bigoplus_{i=0}^{s_w+1} F^{\star}_{w,\mathcal{D}^w_i\ bool},$$

  we can show

  $$\bigoplus_{i=0}^{s_u+1} \left(F^{\star}_{v,\mathcal{D}^v_i\ bool} \oplus F^{\star}_{w,\mathcal{D}^w_i\ bool} \right) \leftrightarrow F_{v\ bool} \oplus F_{w\ bool}.$$

  Namely:

  $$\bigoplus_{i=0}^{s_u+1} F^{\star}_{u,\mathcal{D}^u_i\ bool} \leftrightarrow F_{u\ bool},$$

  as we have assumed that u is a sum gate.

- If u is a product gate with children v, w, using the same notation as above, for $j = 0, 1, \ldots, s_u + 1$, we define $F^{\star}_{u,\mathcal{D}^u_j} := \sum_{i=0}^{j} F^{\star}_{v,\mathcal{D}^v_i} \cdot F^{\star}_{w,\mathcal{D}^w_{j-i}}$. If $j > u_s$, let $F^{\star}_{u,\mathcal{D}^u_j} := 0$. Similarly, using induction hypothesis on nodes v, w and observing the fact that in the formula $s_u = s_v + s_w + 1$, we can prove:

$$F_{u\ bool} \leftrightarrow \bigoplus_{i=0}^{s_u+1} F^{\star}_{u,\mathcal{D}^u_i\ bool}$$

as follows:

$$\begin{aligned}
&F_{u\ bool}\\
\leftrightarrow &F_{v\ bool} \wedge F_{w\ bool}\\
\leftrightarrow &\left(\bigoplus_{j=0}^{s_v+1} F^{\star}_{v,\mathcal{D}^v_j\ bool}\right) \wedge \left(\bigoplus_{i=0}^{s_w+1} F^{\star}_{w,\mathcal{D}^w_i\ bool}\right)\\
\leftrightarrow &\bigoplus_{j=0}^{s_v+s_w+2} \bigoplus_{i=0}^{j} \left(F^{\star}_{v,\mathcal{D}^v_i\ bool} \wedge F^{\star}_{w,\mathcal{D}^w_{j-i}\ bool}\right)\\
\leftrightarrow &\bigoplus_{j=0}^{s_u+1} \left(\bigoplus_{i=0}^{j} \left(F^{\star}_{v,\mathcal{D}^v_i\ bool} \wedge F^{\star}_{w,\mathcal{D}^w_{j-i}\ bool}\right)\right)\\
\leftrightarrow &\bigoplus_{i=0}^{s_u+1} F^{\star}_{u,\mathcal{D}^u_i\ bool}.
\end{aligned}$$

□

5.5 Homogenous non-commutative formula identities have polynomial-size Frege proofs

To conclude Theorem 14 it remains to prove Lemma 19. Here we will prove 19, based on further lemmas we prove in the next section.

First, we need to set some notation. Denote by $F =^{syn} G$ the fact that F is syntactically identical to G. And for two *vectors* of formulae $\overline{F}, \overline{G}$, denote by $\overline{F} =^{syn} \overline{G}$ the fact that the two vectors are identical coordinate-wise.

Definition 17 (Syntactic-degree)**.** *Define the* syntactic degree *of a non-commutative formula F, $deg(F)$, as follows: (i) If F is a field element or a variable, then $deg(F) = 0$ and $deg(F) = 1$, respectively; (ii) $deg(F \oplus G) = max(deg(F), deg(G))$, and $deg(F \otimes G) = deg(F) + deg(G)$, where $\oplus, \otimes$ denote plus gates, product gates respectively.*

The following definition is essential for the next section, where we talk about algebraic branching programs (ABPs). This definition will enable us to identify within a homogenous non-commutative formula a certain part of the formula that corresponds to a part of the algebraic branching program.

Definition 18 (Induced part of a formula)**.** *Let F' be a sub-formula of F and $g_1, ..., g_k$ be gates in F' and $c_1, ..., c_k$ be constants in $\mathbb{F}$. Then $F'[c_1/g_1, ..., c_k/g_k]$ is called* an induced part of F.

We sometimes call an induced part of a formula simply a *part of a formula*.

Lemma 19 (Main technical lemma)**.** *There exists a constant c such that if a non-commutative* homogeneous *formula $F(\overline{x})$ over $GF(2)$ of size s is identically zero, then the corresponding Boolean tautology $\neg F_{bool}(\overline{p})$ can be proved with a Frege proof of size at most s^c (for sufficiently large s).*

Proof. Let d be the syntactic-degree of F. Note that the syntactic-degree d of F is at most $s+1$. Theorem 20, proved in the next section, states the existence of a collection of witnesses that witness that the homogenous non-commutative formula F computes the non-commutative zero polynomial. As demonstrated below, these witnesses, derived from the Raz and Shpilka [RS05] PIT algorithm for non-commutative formulas, will enable us to inductively and efficiently prove in Frege that F indeed is the zero polynomial (over GF(2)). The following are the witnesses and the properties they have:

Identity Witnesses

1. $d+1$ many 0-1 matrices Λ_i of the following dimensions: for $i = 0, \ldots, d-1$, Λ_i is of dimension $m_i \times m_i$; for $i = d$, Λ_d is of dimension $1 \times m_d$, where $m_d = 1$ (so $\Lambda_d = 1$).

2. d many matrices $\mathbf{T}_{i-1}$; For each matrix $\mathbf{T}_{i-1}, i = 1, \ldots, d$, its $m_i \times m_{i-1}$ entries are homogenous linear forms in the $\overline{x}$ variables with 0-1 coefficients.

3. For $i = 0, \ldots, d$, $\overline{F}_i$ is a vector of induced parts of F, each computing a homogenous non-commutative polynomial of degree exactly i. The length of the vectors $\overline{F}_i$ is denoted m_i.

These witnesses make the following equalities true:

$$\Lambda_i \overline{F}_i = \overline{0}, \quad i = 0, 1, \ldots, d, \tag{12}$$

$$F =^{syn} \Lambda_d \overline{F}_d \text{ (meaning that } F =^{syn} \overline{F}_d) \tag{13}$$

$$\Lambda_i \overline{F}_i =^{syn} \mathbf{T}_{i-1} \Lambda_{i-1} \overline{F}_{i-1} \qquad i = 1, \ldots, d. \tag{14}$$

To conclude Lemma 19 we demonstrate a proof of $\neg F_{bool}$ based on the tautological Boolean formulas obtained from equations (12), (13) and (14). For simplicity of transforming (12), (13), (14) to Boolean formulas, denote $\overline{F_{bool}(\overline{p})}_i$ as the vector of all corresponding Boolean formulas of the formulas in $\overline{F}_i$, and $\overline{F_{bool}(\overline{p})}_{i,t}$ as its t^{th} coordinates.

Based on (12), we have the following Boolean formulae:

$$\bigwedge_{w \in [m_i]} \left(\bigoplus_{t:\Lambda_i(w,t)=1} \neg \left(\overline{F_{bool}(\overline{p})}_{i,t} \right) \right), \qquad i = 0, 1, \ldots, d. \tag{15}$$

And based on (14), for $i = 1, \ldots, d$, and each index $u \in [m_i]$ of vector $\Lambda_i \overline{F}_i$, we have the following logical equivalence between two Boolean formulae:

$$\left(\bigoplus_{t:\Lambda_i(u,t)=1} \neg \overline{F_{bool}(\overline{p})}_{i,t} \right) \equiv \bigoplus_{w \in [m_i]} \left(\mathbf{T}_{i-1}(u,w)_{bool}(\overline{p}) \wedge \left(\bigoplus_{t:\Lambda_{i-1}(w,t)=1} \neg \overline{F_{bool}(\overline{p})}_{i-1,t} \right) \right), \tag{16}$$

which states the equivalence between *two consecutive* Boolean formulae in 15. Note that $\mathbf{T}_{i-1}(u,w)$ is a linear combination $\sum_{i=1}^{n} c_i x_i$ where $c_i \in GF(2), \forall i \in [n]$. Thus

$$\mathbf{T}_{i-1}(u,w)_{bool}(\overline{p}) = \bigoplus_{i:c_i=1} p_i.$$

Now we give a Frege proof of the Boolean formulae (15), (16). First, (16) can be immediately proved in Frege since the left part is syntactically equal to the right part (by the syntactic equalities in (14)). Moreover, when $i = 0$, $\overline{F}_0$ is just a 0-1 constant vector. Thus, the following Boolean formula is a tautology without variables and hence can be proved in Frege in polynomial-size:

$$\bigwedge_{w \in [m_0]} \left(\bigoplus_{t:\Lambda_i(w,t)=1} \neg \overline{F_{bool}(\overline{p})}_{i,t} \right). \tag{17}$$

Therefore, applying modus ponens inductively on (17) and (16) we can prove each tautology in (15). Hence, when $i = d$, we have proved:

$$\bigwedge_{w \in [m_d]} \left(\bigoplus_{t:\Lambda_d(w,t)=1} \neg \overline{F_{bool}(\overline{p})}_{d,t} \right),$$

which is just $\neg F_{bool}(\overline{p})$ by (13). □

5.6 Identity witnessing theorem

It remains to prove the following:

Theorem 20 (Identity witnessing theorem)**.** *Let $F(\overline{x})$ be a non-commutative homogenous formula of syntactic degree d over $GF(2)$ computing the non-commutative zero polynomial. Then the Identity Witnesses as defined in Section 5.5 exist.*

In what follows we will prove this theorem. The proof uses the notion of an algebraic branching program and the Raz and Shpilka PIT algorithm [RS05].

5.6.1 Algebraic branching programs

We recall the work of Raz and Shpilka [RS05] showing a deterministic polynomial-time PIT algorithm for non-commutative arithmetic formulas. Similar to [RS05], we introduce the following definition:

Definition 19 (ABP)**.** *An algebraic branching program (ABP) is a directed acyclic graph with one source and one sink. The vertices of the graph are partitioned into levels numbered from* 0 *to* d *(the degree of the ABP), and edges may go only from level* i *to level* $i+1$*. The source is the only vertex at level* 0*, and the sink is the only vertex at level* d*. Each edge is labeled with a homogeneous linear polynomial in the variables* x_i *(i.e., a function of the form* $\sum_i c_i x_i$*, with coefficients* $c_i \in \mathbb{F}$*, where* $\mathbb{F}$ *is the underlying field). The* size *of an ABP is the number of its vertices. A path, directed from source to sink, in the ABP is said to* compute *the non-commutative product of linear forms on its edges (in the order they appear in the path). A node in the ABP* computes *the sum of all incoming paths arriving from the source. The ABP* computes *the non-commutative polynomial computed at its sink.*

By transforming the formula to ABP and using the following fact which had been proved in [RS05], one can obtain a deterministic polynomial-time algorithm for the polynomial identity testing of non-commutative formulas:

Theorem 21 (Theorem 4, [RS05])**.** *Let* A *be a (non-commutative) ABP of size* s *with* $d+1$ *levels then we can verify whether* A *is a zero polynomial in time* $O(s^5 + s \cdot n^4)$*.*

Let l be the number of levels in the ABP A where the source node is on the 0^{th} level and the sink node is on the $(l+1)^{th}$ level. Denote the nodes on the i^{th} level by $v_{i,1}, \ldots, v_{i,m_i}$ (where m_i is the number of nodes on the i^{th} level). Thus the ABPs starting from each node on the i^{th} level to the sink v_{l+1} compute the i-degree polynomials: $A(v_{l+1-i,1}, v_{l+1}), \ldots, A(v_{l+1-i,m_{l+1-i}}, v_{l+1})$. Furthermore, for $i = 0, 1, \ldots, l+1$, denote by:

$$\overline{A_i} := \left(A(v_{l+1-i,1}, v_{l+1}), \ldots, A(v_{l+1-i,m_{l+1-i}}, v_{l+1})\right)$$

the vector of these polynomials. With this notation, we are now able to apply a similar idea to that in Raz and Shpilka's PIT algorithm for non-commutative formulas [RS05]:

Lemma 22. *If* $A(v_0, v_{l+1})$ *is identically zero, then:*

1. *There exist* $l+1$ *0-1 matrices* Λ_i *with dimension* $m_i \times m_i$ *such that*

$$\Lambda_i \overline{A_i} = \overline{0}, \quad i = 0, \ldots, l,$$

   (where the equality here is semantic).

2. *There exist* l *matrices* $\mathbf{T}_{i-1}$ *whose* $m_i \times m_{i-1}$ *entries are homogenous linear forms in the* $\overline{x}$ *variables with 0-1 coefficients, such that*

$$\Lambda_i \overline{A_i} =^{syn} \mathbf{T}_{i-1} \Lambda_{i-1} \overline{A_{i-1}}, \quad i = 1, \ldots, l-1$$

$$A(v_0, v_{l+1}) =^{syn} \overline{A_{l+1}} =^{syn} \mathbf{T}_l \Lambda_l \overline{A_l},$$

   where the syntactic equality means that the ABPs are all identical (when we construct the ABPs in the right hand sides of the two equalities above in the obvious manner).

Proof. Let $\Lambda_{l+1} := 1$. Then we know:

$$\Lambda_{l+1}\overline{A_{l+1}} = \mathbf{T}_l \Lambda_l \overline{A_l}.$$

We will start from Λ_{l+1} and compute Λ_i inductively for $i = l, \ldots, 0$.

Let $M_{i,i-1}$ be the adjacency matrix of dimension $m_i \times m_{i-1}$ of the two consecutive layers $l-i, l-i+1$ in A, where for each entry:

$$M_{i,i-1}(p,q) = A(v_{l-i,p}, v_{l+1-i,q}) = \sum_{k=1}^{n} c_k x_k,$$
$$\text{where } c_k \in \{0,1\}, k \in [n], p \in [m_i], q \in [m_{i+1}].$$

That is, $M_{i,i-1}$ can be written as $\sum_{k=1}^{n} x_k M_{i,i-1}^{(k)}$ (the superscript (k) is used here as an index only, not as a homogenous component of a polynomial). Therefore, by the definition of an ABP we have:

$$\begin{aligned}\overline{A_i} &= M_{i,i-1}\overline{A_{i-1}} \\ &= \sum_{k=1}^{n} x_i M_{i,i-1}^{(k)} \overline{A_{i-1}}.\end{aligned}$$

Moreover, if $\Lambda_i \overline{A_i} = \overline{0}$, then

$$\Lambda_i \sum_{k=1}^{n} x_i M_{i,i-1}^{(k)} \overline{A_{i-1}} = 0.$$

Therefore, by the non-commutativity of product we have:

$$\Lambda_i M_{i,i-1}^{(k)} \overline{A_{i-1}} = 0, \ k = 1, 2, \ldots, n.$$

Hence, to prove the existence of Λ_{i-1} for which the statement of the lemma holds, it suffices to find a Λ_{i-1} that satisfies the following property:

$$\Lambda_{i-1}\overline{A_{i-1}} = 0 \quad \Longleftrightarrow \quad \Lambda_i M_{i,i-1}^{(k)} \overline{A_{i-1}} = 0, \ k = 1, 2, \ldots, n.$$

This can be done by finding the basis of the span of all row vectors in $\Lambda_i M_{i,i-1}^{(k)}, \quad k = 1, 2, \ldots, n$.

Moreover, to prove the existence of $\mathbf{T}_{i-1}^{(k)}$ we note that, by properties of a basis of a linear space, there must be a matrix $\mathbf{T}_{i-1}^{(k)}$ such that:

$$\Lambda_i M_{i,i-1}^{(k)} = \mathbf{T}_{i-1}^{(k)} \Lambda_{i-1}, \ k = 1, 2, \ldots, n$$

Then, let $\mathbf{T}_{i-1} = \sum_{k=1}^{n} \mathbf{T}_{i-1}^{(k)} x_k$. Thus:

$$\Lambda_i \cdot \overline{A_i} = \mathbf{T}_{i-1} \Lambda_{i-1} \overline{A_{i-1}}.$$

□

5.6.2 Implicitly working with ABPs

Notice that it is unclear how to (usefully) represent an ABP A directly in Frege system, because apparently ABP is a stronger model than formulas (and Frege operates with formulas). Thus, we cannot directly use the same formulation as [RS05]. This is the reason we work with induced parts of formulas (Definition 18): an induced part of a formula serves as a "massaged" version of a part of the ABP obtained from the non-commutative formula.

Denote by A the ABP obtained from F. For two vertices v', v'' in the ABP A, we denote by $A(v', v'')$ the polynomial computed by the ABP with the source v' and the sink v'' and all paths leading from v' to v''.

We observe that Raz and Shpilka's [RS05] proof uses only those ABPs $A(v, v_{l+1})$ in which v is an arbitrary node in A and v_{l+1} is the sink. We introduce the following definition:

Definition 20 (v-part of formula F)**.** *Let F be a homogenous formula and A be an ABP transformed from F according to the methods stated in [RS05] in which the source is v_0 and the sink is v_{l+1}. For every node v in A, if there exists an induced part of the formula F computing the same polynomial as $A(v, v_{l+1})$, then we call this part a* v-part of the formula F *(the v-part is not necessarily unique).*

Let F be a non-commutative homogenous formula and let A be the corresponding ABP of F. By Lemma 23 (proved in the sequel) we construct ***an injective map*** between the nodes v in A to v-parts of F, denoted $F_v^\bullet$ (so $F_v^\bullet$ computes the non-commutative homogenous polynomial computed by $A(v, v_{l+1})$). Thus, we can refer to every ABP $A(v, v_{l+1})$ implicitly by an explicit induced part $F_v^\bullet$ of F. Furthermore, for every vertex v in A, we know that there exists an order of summation (written as a fan-in two formula of plus gates) and also a linear sum (also written as a formula of plus gates) making the following *syntactic* equality true:

$$F_v^\bullet =^{syn} \sum_{\substack{u:\ u \text{ has an incoming} \\ \text{edge from } v}} A(v,u) \times F_u^\bullet. \tag{18}$$

We show how to inductively construct the injective mapping $F_v^\bullet$ between nodes v in the ABP A and v-parts in F in the proof of the following lemma:

Lemma 23. *For a non-commutative homogenous formula F with 0-1 coefficients, let A be the ABP transformed from F by the methods in [RS05, Nis91] in which the source is v_0 and the sink is v_{l+1}. For every node v in A the polynomial computed by $A(v, v_{l+1})$ can be computed by some formula, denoted $F_v^\bullet$, which is a v-part of F. Furthermore, for every node v in the ABP, there exits an order of summation (written as a fan-in two tree of plus gates) and a sequence of formulas computing homogenous linear forms $A(v,u)$ (identified with $A(v,u)$ for simplicity) such that (18) holds.*

Proof. Let F' be a sub-formula of F and let $g_1, ..., g_k$ be gates in F' and $c_1, ..., c_k$ constants in $\{0, 1\}$. Recall that we call $F'[c_1/g_1, , \ldots, , c_k/g_k]$ *an induced part of* F. First, we construct a *non-homogeneous* ABP $\mathfrak{A}$, such that each node v of $\mathfrak{A}$ is mapped to a part of F, (which we denote for simplicity also $F_v^\bullet$). In a *non-homogeneous ABP* we mean that

the ABP is not necessarily leveled, that edges may be labeled with constants 1, and that the ABP may output a non-homogeneous polynomial.

Similar to the standard construction in [RS05], construct by recursion a non-homogeneous ABP for the right son of the root of the formula and a non-homogeneous ABP for the left son of the root of the formula. We denote with v_0 and v_{l+1} the source and the sink, respectively, of the resulting ABP.

We will assign the corresponding $F_v^\bullet$ to v once we add the node v in $\mathfrak{A}$.

Consider the process of construction: each time we have two nodes v_1, v_2 which had been added and we proceed to construct, by induction, $\mathfrak{A}(v_1, v_2)$ for the formula F'. In other words, we add nodes between v_1, v_2 according to the arithmetic operation in the root gate g, continuing the construction on the son gates of g.

We now give the details of how to add nodes according to the arithmetic operation in g as well as how to assign specific parts of F to these new nodes.

- If g is a plus gate, add two new nodes v', v'' and wire the ABPs in parallel as follows: add two edges labeled with 1 from v_1 to v' and from v_1 to v''. Furthermore, we continue the construction of $\mathfrak{A}(v', v_2), \mathfrak{A}(v'', v_2)$ for $F'_{g_{left}}, F'_{g_{right}}$, respectively.

  Then, the corresponding v-parts $F^\bullet_{v'}, F^\bullet_{v''}$ of F for v', v'' should compute the same polynomials computed by $\mathfrak{A}(v', v_{l+1}), \mathfrak{A}(v'', v_{l+1})$.

  Consider the gate g in the original F, $F_g = F_{g_{left}} + F_{g_{right}}$. Furthermore, consider g in F', $F'_g = F'_{g_{left}} + F'_{g_{right}}$.

$$\begin{aligned}
\mathfrak{A}(v', v_{l+1}) &= \mathfrak{A}(v', v_2) \cdot \mathfrak{A}(v_2, v_{l+1}) \\
&= F'_{g_{left}} \cdot F^\bullet_{v_2} \\
&= (F' - F'_{g_{right}}) \cdot F^\bullet_{v_2} \\
&= F'[0/g_{left}] \cdot F^\bullet_{v_2} \\
&= \left(F' \cdot F^\bullet_{v_2}\right)[0/g_{left}] \\
&= F^\bullet_{v_1}[0/g_{left}].
\end{aligned}$$

  Note that $F^\bullet_{v_1}[0/g_{left}]$ is also a part of F and we assign it to v' as the corresponding v-part $F^\bullet_{v'}$. Similarly, for node v'', the part $F^\bullet_{v_1}[0/g_{right}]$ is assigned as the v-part.

- If g is a product gate, add the node v and wire $\mathfrak{A}$ sequentially with node v_1, v, v_2 such that $\mathfrak{A}(v_1, v) = F_{g_{left}}, \mathfrak{A}(v, v_2) = F_{g_{right}}$. Then the corresponding v-part of F for the new node v should satisfy the following:

$$F^\bullet_v = F'_{g_{right}} \cdot F^\bullet_{v_2} = F'[1/g_{left}] \cdot F^\bullet_{v_2} = F^\bullet_{v_1}[1/g_{left}].$$

  Thus we can assign $F^\bullet_{v_1}[1/g_{left}]$ to v as the corresponding v-part of F.

That is, each node v of $\mathfrak{A}$ corresponds to a unique part $F^\bullet_v$ of F computing $\mathfrak{A}(v, v_{l+1})$.

Observe that every edge in the non-homogenous ABP $\mathfrak{A}$ is labeled by only one constant or only one variable. Using the above notation, we have the following syntactic equality: when v', v'' are children of a plus gate v_1, then

$$F^\bullet_{v_1} =^{syn} F^\bullet_{v_1}[0/g_{right}] + F^\bullet_{v_1}[0/g_{left}] =^{syn} F^\bullet_{v'} + F^\bullet_{v''}.$$

When v is introduced by a product gate v_1 and v and both gates are directly connected by an edge labeled with x, then:

$$F^{\bullet}_{v_1} =^{syn} \mathfrak{A}(v_1, v)F^{\bullet}_{v_1}[1/v] =^{syn} x \cdot F^{\bullet}_{v}.$$

Moreover, notice that such parts $F^{\bullet}_{v}$, where v is a node of $\mathfrak{A}$, is also a homogenous formula as we only substitute the son gates of plus gates or product gates by 0, or 1, respectively, maintaining these plus and product gates still computing the homogenous formula.

Like [RS05], to turn the non-homogeneous ABP to a standard ABP, first replace each vertex v (except the source) of the non-homogeneous ABP with $s+1$ new vertices, $(v,0),(v,1),\ldots,(v,s{+}1)$, such that vertex (v,i) computes the homogeneous part of degree i of v, namely $F_v^{\bullet\,(i)}$. However, by the property of a homogenous formula, we know there is only one node (v,i) in the $s+1$ copies computing the exact $F^{\bullet}_{v}$ but 0. Therefore, we only need to focus on the unique copy computing the non-zero polynomial among these ABPs and such copy, denoted by A', is the same as $\mathfrak{A}$, except the original names v of each node in $\mathfrak{A}$ becomes (v,i_v) where i_v is the degree of the homogenous polynomial computed by $F^{\bullet}_{v}$.

Then all that we need to do to turn A' into a standard (homogenous) ABP is to get rid of edges labeled with constants. Note that the following operations, for getting rid of edges labeled with constants, can only reduce the number of nodes in an ABP while not changing any correspondence between the nodes in the ABP and the sub-formulae of F. Therefore, we can conclude that for each node v in A, the formula computed by $A(v, v_{l+1})$ can be computed by the formula $F^{\bullet}_{v}$ which is an induced part of F. Additionally, the following operations do not change the syntactical equivalence between each nodes on different levels but may make several equalities into one with some specific order. *** ? *** For simplicity, we denote it as

$$F^{\bullet}_{v} =^{syn} \sum_{\substack{u \text{ has incoming} \\ \text{edge from } v}} A(v,u) \times F^{\bullet}_{u}.$$

We now get rid of edges that are labeled with constants. Since the coefficient is either 0 or 1 and the edge with 0 can be erased directly as it has no influence on the result, all edges that we proceed to get rid of is those with constant 1

Let e be a such edge labeled with a constant 1.

For every edge e going from (v,i_v) to (u,i_u) for some nodes u,v of F: we erase the edge e, and instead we connect every (directed) in-neighbor of (v,i_v), (w,i_w) if $i_w = i_v - 1$, to (u,i_u) in the following manner: If the edge from (w,i_w) to (v,i_v) is labeled with some function h, then we put a directed edge between (w,i_w) and (u,i_u) and label it with h. If there is already an edge between (w,i_w) and (u,i_u), labeled with some function h_0, then we replace it with an edge labeled with $h_0 + h$.

To conclude, we finish the transformation from a homogenous formula F to an ABP A, where for each node v in A, we have a v-part of F, denoted $F^{\bullet}_{v}$, that computes the polynomial computed by $A(v, v_{l+1})$; and further there exits a specific order of summation (written as a fan-in two tree of sum gates) and specific formulas computing homogenous

linear forms $A(v,u)$, such that:

$$F_v^\bullet =^{syn} \sum_{\substack{u \text{ has incoming} \\ \text{edge from } v}} A(v,u) \times F_u^\bullet.$$

□

Now we conclude the proof the main Theorem 20, as follows:

Proof of Theorem 20. For the non-commutative homogenous formula $F(\overline{x})$ with 0-1 coefficients computing a zero polynomial, let $A(v_0, v_{l+1})$ be its corresponding ABP, which means $A(v_0, v_{l+1})$ is identically zero.

Then by Lemma 22 we know:

(i) there exists $l+1$ 0-1 matrices Λ_i with dimension $m_i \times m_i$ such that

$$\Lambda_i \overline{A_i} = \overline{0}, \quad i = 0, \ldots, l;$$

(ii) there exists l matrices $\mathbf{T}_{i-1}$ whose $m_i \times m_{i-1}$ entries are homogenous linear forms in the $\overline{x}$ variables with 0-1 coefficients, such that

$$\Lambda_i \overline{A_i} = \mathbf{T}_{i-1} \Lambda_{i-1} \overline{A_{i-1}}, i = 1, \ldots, l-1,$$
$$A(v_0, v_{l+1}) = \overline{A_{l+1}} = \mathbf{T}_l \Lambda_l \overline{A_l}.$$

Using the correspondence given in Lemma 23, we can replace each ABP $A(v, v_{l+1})$ in $\overline{A_i}$ by a corresponding v-part $F_v^\bullet$. Denote with $\overline{F}_i$ the vector of all v-parts $F_v^\bullet$ of F that compute a (homogenous) polynomial of degree i, we can replace $\overline{A_i}$ in the above equalities to obtain new equalities about parts of formula F rather than APBs. Note that there may be some redundant v-parts of F in $\overline{F}_i$ which do not correspond to any node in ABP, we can just add more lines with all zero in Λ_i to get rid of them. For simplicity, in what follows, we still use Λ_i to denote such matrices with additional zero lines.

Now, we have:

(i) $d+1$ 0-1 matrices Λ_i of dimension $m_i \times m_i, i = 0, \ldots, d-1$ and Λ_d of dimension $1 \times m_d$, such that

$$\Lambda_i \overline{F}_i = \overline{0}, \quad i = 0, 1, \ldots, d,$$

and

(ii) d matrices $\mathbf{T}_{i-1}$ whose $m_i \times m_{i-1}$ entries are homogenous linear forms in the $\overline{x}$ variables with 0-1 coefficients, such that

$$\Lambda_i \overline{F}_i = \mathbf{T}_{i-1} \Lambda_{i-1} \overline{F}_{i-1}, \qquad i = 1, \ldots, d.$$
$$F = \Lambda_d \cdot \overline{F}_d.$$

Using the syntactic equality in Lemma 23, we know there exits a specific order of summation and specific formulas computing homogenous linear forms making equalities in 5.6.2, 5.6.2 be syntactic equalities:

$$\Lambda_i \overline{F}_i =^{syn} \mathbf{T}_{i-1} \Lambda_{i-1} \overline{F}_{i-1}, \qquad i = 1, \ldots, d.$$
$$F =^{syn} \Lambda_d \cdot \overline{F}_d.$$
