ABSTRACT

The logic-programming paradigm is a prime example of how the integration of the declarative and the operational aspects of logical systems can be used to provide a unified framework for both specification and programming languages. In essence, programming in logic amounts to giving appropriate axiomatic formalizations of computable functions, which can then be executed by means of carefully designed goal-directed deduction rules.

In this thesis, we examine common features of various conventional logic-programming languages, ranging from the most traditional variant of the paradigm – defined over Horn-clause logic – to first-order and higher-order equational logic programming. Based on these, we propose an abstract model-theoretic framework that allows us to develop and conduct research into logic programming over an arbitrary logical system, without concrete models, sentences, satisfaction, or deduction, and thus to explore the logic-programming paradigm for other, less conventional formalisms, like the logic of orchestration schemes used in the context of service-oriented computing.

Our study is based on abstractions of notions such as logic program, clause, query, solution, and computed answer, which we develop over Goguen and Burstall’s theory of institutions. These give rise to a series of concepts that formalize the interplay between the denotational and the operational semantics of logic programming. We investigate properties concerning the satisfaction of quantified sentences, discuss a variant of Herbrand’s theorem that is not limited in scope to any logical formalism or construction of logic programs, and define a sound and conditionally complete procedure for computing solutions to queries. Within this setting, we further examine two of the most fundamental aspects of the modularization of logic programs – the preservation and the reflection of solutions along morphisms of programs – leading to results that can be applied not only to unstructured logic programs (plain sets of clauses), but also to elaborate module systems.
ACKNOWLEDGEMENTS

The material in this thesis is a natural extension of a series of developments in institutional abstract model theory, algebraic specification, and logic programming. I would like to thank the members of these communities, and some of them in particular below, for their contributions to logic and computer science, without which this research would not have been possible.

First of all, I would like to express my deepest gratitude to my supervisor, José Luiz Fiadeiro, for his guidance, dedication, and support during my PhD studies, and generally for giving me the opportunity to investigate the logic-programming paradigm from an institutional point of view. His research questions, ideas, and critical feedback have been invaluable for the completion of this project and for my development as a researcher.

Special thanks go to Răzvan Diaconescu for introducing me to the elegant theory of institutions and for his constant encouragement and friendship. I also owe a great deal to Virgil Căzănescu, Mihai Codescu, Daniel Găină, Antónia Lopes, Till Mossakowski, Fernando Orejas, and Uwe Wolter for many pleasant and inspiring discussions, all of which have contributed to the present form of this thesis. My research has benefited from the constructive advice and feedback of the members of the Department of Computer Science at the University of Bucharest, who kindly invited me to present different aspects of my work, at various stages of their development, whenever I visited my home country. In addition, I would like to acknowledge the members of Department of Computer Science at Royal Holloway University of London for creating a friendly and welcoming atmosphere, as well as a good research environment. I am very grateful for all of that.

Last but far from least, I would like to thank my parents, Oana, and Claudia for being supportive, patient, and understanding throughout these years.

This research has been partly funded by an EPSRC Doctoral Training Grant between 2011 and 2012, a Reid Scholarship awarded by Royal Holloway University of London from 2012 onward, and by a grant of the Romanian National Authority for Scientific Research, PN-III-P1-1.1-PF-2016-0378.

INTRODUCTION

This thesis concerns the model-theoretic foundations of logic programming from the vantage point of the theory of institutions put forward by Goguen and Burstall in the late 1970s in the context of algebraic specification. Its purpose is to provide a general mathematical framework for the study of logic programming so that, through abstraction, one could gain a more accurate and deeper understanding of the intrinsic nature of the paradigm. In this introduction, we discuss the motivation that underlies the present research and give an overview of the following chapters.

1.1 THE LOGIC-PROGRAMMING PARADIGM

The essential idea of exploring the computational aspects of logical inference as a foundation for the development of new programming paradigms was first investigated by Kowalski [KK71; Kow74] and Colmerauer [Col+73] based on the pioneering work of Herbrand in proof theory [see Her67] and on the introduction by Robinson [Rob65] of resolution as an inference rule well suited for automation. Logic programming thus originated from the observation that a considerable fragment of first-order logic has a natural computational interpretation that makes it adequate not only as a declarative language but also as a programming language. To be more precise, logic programming (a) defines computable functions by way of standard constructs from model theory and (b) executes these definitions as programs through goal-directed deductions that are performed according to a fixed strategy. This means that logic programming provides, at the same time, both a denotational and an operational perspective on programs.

Conventional logic programming is semantically based upon the Horn-clause fragment of (single-sorted) first-order logic without equality, and implements deduction as backwards reasoning defined in terms of resolution steps [see Llo87]. However, the essence of the paradigm is, to a great extent, independent of any logical system of choice. This is reflected by a multitude of variants that have been developed over time, such as order-sorted [GM86]
and category-based equational logic programming [Dia95], constraint logic programming [JL87] (see also [Dia00] for a presentation that is more closely related to the setting of this thesis), as well as higher-order [Mes89; Mes92] and behavioural (i.e. object-oriented) logic programming [GMK02]. Even more, recent developments in the operational semantics of systems in the context of service-oriented computing [see e.g. FLB11] have suggested a deep connection with logic programming. This connection was made explicit in [ŢF13] with the introduction of a service-oriented variant of the paradigm, which we will further pursue in Chapter 5 of this thesis.

1.2 TOWARDS ABSTRACT LOGIC PROGRAMMING

Through our inquiry, we aim to provide a single unifying framework for the model-theoretic foundations of logic programming, with a high level of abstraction, that incorporates ideas from concrete instances of the phenomena but without being committed to any particular formalism. To this end, our work has roots in the theory of institutions [GB92] – a major field of study in universal logic that originated in computer science – and draws inspiration from previous institution-theoretic developments related to logic programming such as [Tar86; Dia04] and also [Mes89]. We propose an axiomatic approach to logic programming, and intrinsically to logic programs, that is founded on a three-level hierarchy of concepts meant to capture:

1 the denotational semantics of logic programming, based on a notion of generalized substitution system that extends institutions with appropriate abstractions of variables, substitutions, local sentences, interpretations (of variables), and satisfaction, all parameterized by the signature used;

2 the operational semantics of logic programming, supported by a notion of logic-programming framework that describes clauses and queries – two of the most important syntactic structures used to define and execute logic programs – as well as goal-directed rules that allow the integration of resolution;

3 the various constructions of logic programs through a notion of logic-programming language that defines programs as abstract objects characterized by signatures, sets of axioms (clauses) and classes of models, thus allowing us to uniformly accommodate a great variety of module systems.

Under this conceptual structure, we study a logic-independent version of Herbrand’s theorem, describe a general resolution-based procedure for computing solutions to queries, introduce a new form of service-oriented logic programming, and develop foundations of modularization.
HERBRAND’S FUNDAMENTAL THEOREM

The Fundamental Theorem of Herbrand [Her67] is a central result in proof theory that deals with the reduction of provability in first-order logic to provability in propositional logic. Its importance in the context of automated theorem proving was realized in the early 1960s, when, together with the theory of Horn-clause logic, it played a key role in establishing the mathematical foundations of logic programming [see e.g. Llo87]. In the traditional setting of relational first-order logic, Herbrand’s theorem states that, for a set $\Gamma$ of Horn clauses (an unstructured logic program), the answers to an existential query can be found simply by examining a term model – the least Herbrand model – instead of all the models that satisfy $\Gamma$. Thus, the theorem links the denotational and the operational semantics of a logic-programming language by reducing the satisfiability of a query with respect to a given logic program to the search of a suitable correct-answer substitution.

Over the last three decades, the original result has been extended to a variety of logical systems [e.g. GM87; Dia00; GMK02], culminating in [Dia04] with an investigation of Herbrand’s theorem in an arbitrary institution. Thanks to its generality, the institution-based approach to Herbrand’s theorem enabled the development of logic programming over a wide range of logical systems [see e.g. Găiip; and also Dia08]. All the same, certain institution-based forms of logic programming do not fit into the framework proposed in [Dia04]. In particular, the logic-programming semantics of services [ŢF13] is grounded on a family of logical systems for which the concept of variable cannot be faithfully captured by means of representable extensions of signatures, thus failing to meet one of the most basic assumptions of the institution-independent variant of the theorem. This led us to study Herbrand’s fundamental theorem in an even greater extent in Chapters 3 and 4, in the general context of abstract logic-programming languages.

SOUND AND COMPLETE OPERATIONAL SEMANTICS

The second main contribution of our work is the development of a sound procedure for searching for solutions to queries. As in conventional logic programming, this is achieved through the computation of a series of intermediate results (namely computed substitutions) by means of resolution steps. The challenge here lies primarily in determining an appropriate formalization of the goal-directed rules that underlie our general form of resolution so as to capture both the first-order resolution of relational logic programming [see Rob65] and the paramodulation of equational logic pro-
gramming [see RW83]. We study the proposed abstract notion of resolution in Chapter 3, where, in addition to soundness, we also discuss a minimal set of assumptions under which it can be shown to be complete.

**SERVICE-ORIENTED LOGIC PROGRAMMING**

Service-oriented computing is a modern computational paradigm that deals with the execution of programs over distributed information-processing infrastructures in which software applications can discover and bind dynamically, at run time, to services offered by providers. Whereas the paradigm has been effectively in use for a more than a decade in the form of Web services [Alo+04] or Grid computing [FK04], research into its formal foundations has lagged somewhat behind, partly because of the lack of understanding of (or agreement on) what is really new about the paradigm, especially in relation to distributed computing in general [see e.g. Vog03].

It is fair to say that significant advances have been made towards formalizing new kinds of distributed computation that have arisen around the notion of service (see, for example, the choreography models discussed in [Su+07]), notably through several variants of the $\pi$-calculus. However, service-oriented computing raises more profound challenges at the level of the structure of systems due to their ability to discover and bind dynamically, in a non-programmed manner, to other systems. As a result, the structure of the systems that we are now creating in the virtual space of computational networks is intrinsically dynamic, a phenomenon hitherto unknown. Formalisms such as the $\pi$-calculus do not address these structural properties of systems. This prevents us from fully controlling and developing trust in the systems that are now operating in cyberspace, and also from exploiting the power of the paradigm beyond the way it is currently deployed.

Towards that end, a great deal of work has focused on the algebraic structures that account for modularity [e.g. FLB07; FS07] – referring to the way services are orchestrated as composite structures of components and how binding is performed through interaction protocols – and on the mechanisms through which discovery can be formalized in terms of logical specifications of required/provided services and constraint optimization for service-level agreements [e.g. FLB11; FL13a]. In Chapter 5, we take this research further to address the operational aspects behind dynamic reconfiguration, i.e. the mechanisms through which applications discover and bind, at run time, to services. Our aim is to develop an abstract, foundational setting – independent of the specific technologies that are currently deployed, such as
SOAP for message-exchange protocols and UDDI for description, discovery, and integration – that combines both the denotational and the operational semantics of services. The most difficult and interesting task is to define an integrated algebraic framework that accounts for (a) logical specifications of services, (b) the way models of those specifications capture orchestrations of components that may depend on externally provided services, and (c) how the discovery of services and the binding of their orchestrations to client applications can be expressed in logical/algebraic terms.

The approach that we plan to develop to meet this challenge builds on the relational variant of logic programming. In a nutshell, the analogy between service-oriented computing and conventional logic programming that we propose to systematically examine in this thesis unfolds as follows:

- The Herbrand universe consists of service orchestrations that have no dependencies on external services – what we refer to as ground orchestrations.
- Variables and terms correspond to dependencies on external services to be discovered and to the actual services made available by orchestrations.
- Service clauses express properties of services required or provided by orchestrations, thus capturing the notion of service module described in [FLB11]. Their declarative semantics is that, when bound to the orchestrations of other service clauses that ensure the required properties, they deliver, through their orchestration, services that satisfy the specified properties.
- Service queries express properties of services that an application requires in order to fulfill its goal – what are described in [FLB11] as activity modules.
- Logic programs define service repositories as collections of service modules.
- Resolution accounts for service discovery by matching required properties with provided ones and the binding of required with provided services.

**Modularization**

The literature on modularization in logic programming is vast, and it has evolved primarily along two somewhat divergent lines of research. Whereas a number of proposals have focused on augmenting logic-programming languages with module systems through dedicated constructs for building programs as hierarchical combinations of components, preserving in this way the denotational and the operational semantics of the underlying formalisms [see e.g. O’K85; GM86; SW92], others have explored the possibility of extending the base language with new logical connectives in order to capture the operators needed for building and composing program modules [see e.g. Mil89; GMR92; and also the comprehensive survey BLM94].
Through our work, we aim to bring the two aforementioned lines of research into harmony by studying modularization over the model-theoretic framework for logic programming advanced in Chapter 3, which combines ideas specific to each of the directions. On the one hand, by extending the concept of institution with appropriate notions of variable, substitution, clause, query, and goal-directed rule, the theory we propose accommodates logical systems whose expressive power goes beyond that of the original formalism of Horn-clause logic. On the other hand, inspired by recent developments in the theory of structured specifications [see Dia12a], it defines logic programs in an axiomatic manner, capturing in this way both representations of programs as plain sets of (definite) clauses [see Llo87] and module systems like those described, for example, in [ST88a; Bor02; DŢ11].

In the final chapter of this thesis, we investigate elementary modularization properties concerning the preservation and the reflection of solutions along morphisms of programs. From a computational point of view, these properties have a significant impact on the efficiency of searching for solutions to queries. In particular, the preservation of solutions gives us the possibility to search for solutions to queries in restricted contexts that correspond to subprograms or imported modules, and then translate these solutions back to the original setting, while the reflection property guarantees that all solutions can be obtained in this manner.

1.3 THE STRUCTURE OF THE THESIS

Chapter 3: Section 3.1 reviews the foundations of conventional logic programming, with explicit emphasis on the abstraction of first-order variables and substitutions, and on the mappings induced by signature morphisms. Section 3.2 introduces the basic notion of generalized substitution system and details the conditions that guarantee the invariance of the satisfaction of universally and existentially quantified sentences (defined over a given generalized substitution system) under change of notation. Section 3.3 is dedicated to the development of abstract logic programming, encompassing the notions of logic-programming framework and language, as well as the first main results of the thesis.

Chapter 4: Section 4.1 is devoted to the logical foundations of two other notable variants of logic programming, (many-sorted) first-order and higher-order equational logic programming. In Section 4.2, we examine a class of substitution systems whose variables are defined through extensions of signatures (of a given institution), and whose substitutions correspond to
the institution-independent notion of substitution; based on this formalization, in Section 4.3 we further investigate the translation of variables along signature morphisms and identify a set of sufficient conditions under which an institution can give rise to a generalized substitution system. Lastly, in Section 4.4 we present a different perspective on the institution-independent versions of Herbrand’s fundamental theorem.

Chapter 5: In Section 5.1, we present a new categorical model of service orchestrations, called orchestration scheme, that enables us to treat orchestrations as fully abstract entities required to satisfy only a few elementary properties. This framework is flexible enough to accommodate, for example, orchestrations in the form of program expressions, as considered in [Fia12], or as asynchronous relational networks similar to those defined in [FL13b]. In our study, such schemes play an essential role in managing the inherent complexity of orchestrations whilst making available, at the same time, the fundamental building blocks of service-oriented logic programming. In Section 5.2, we define a logical system of orchestration schemes over which we can express properties that can be further used to guide the interconnection of orchestrations. We prove that the resulting logic forms a generalized substitution system, thus providing the declarative semantics of our approach to service-oriented computing, as well as a definite mathematical foundation to the analogy between service-oriented computing and conventional logic programming. Building on these results, we show how (definite) clauses, queries, unification and resolution can be defined over the generalized substitution system of orchestration schemes, obtaining in this way the corresponding operational semantics of service-oriented computing.

Chapter 6: In Section 6.1, we recall some of the most important specification-building operators from the literature, and explain how they can be used to define modular logic programs. This provides us with a structured model-oriented alternative to the original view of logic programs as plain sets of clauses. Section 6.2 is devoted to the translation of queries and to the preservation and the reflection of solutions along signature morphisms. In Section 6.3, we extend these results to computed answers (i.e. to the more operational notion of solution to a query), and discuss the soundness and completeness of resolution with respect to modularization.
1.4 RELEVANT PUBLICATIONS

Parts of this thesis have been presented at academic conferences, workshops, or meetings, or have been advanced in research papers, as follows:

- **Chapter 3** is a modified version of the paper [TFipa], and has been presented at the 22nd meeting of the IFIP-TC1 Working Group on Foundations of System Specification – IFIP WG1.3.

- **Chapter 4** is based on the results presented in the papers [Tuṭi3; TFipb], of which [TFipb] has been presented at the 6th Conference on Algebra and Coalgebra in Computer Science – CALCO 2015.

- **Chapter 5** is a modified version of the paper [TFipc]; a preliminary version of this work has been presented at the 5th Conference on Algebra and Coalgebra in Computer Science – CALCO 2013 – [TF13].

- **Chapter 6** is to some extent based on the results included in the paper [TFipa], which have been further developed and presented at the 22nd International Workshop on Algebraic Development Techniques – WADT 2014.
TECHNICAL PRELIMINARIES

In this chapter, we review some of the most important category- and institution-theoretic concepts, notations, and terminology that support the general approach to logic programming developed in the subsequent sections of the present thesis. We focus particularly on comma categories, indexed categories, institutions and co-morphisms of institutions, as well as on the presentation of institutions as functors into the category of rooms, all of which will be used extensively in our work.

2.1 CATEGORIES

We assume the reader is familiar with basic notions of category theory such as category, functor, and natural transformation. With a few exceptions, we use the terminology and the notations from [Mac98]. In this sense, we denote by $|C|$ the collection of objects of a category $C$, by $C(A, B)$ the collection of arrows from $A$ to $B$, by $f \circ g$ the composition of arrows $f$ and $g$ in diagrammatic order, and by $1_A$ the identity arrow of an object $A$; furthermore, we denote by $\tau \circ \sigma$ the ‘vertical’ composition of natural transformations $\tau$ and $\sigma$, and by $\tau \cdot \sigma$ (or sometimes by simple juxtaposition) their ‘horizontal’ composition.

A NOTE ON FOUNDATIONS. Most of the constructions described in this thesis rely on large or very large collections of objects, and thus some care must be taken with respect to the set-theoretic foundations of category theory. One may consider for instance the hierarchy of set universes discussed in [Mac98], in which every universe is closed under the usual set-theoretic constructions, contains the elements of its elements, and belongs to the next universe in the hierarchy. In this way, we obtain concepts such as category and functor for every level of the hierarchy, which means that we cannot define, for example, the category of all sets, but rather a category of sets for every universe. In terms of notation, given an arbitrary but fixed level of the hierarchy of set universes, we denote by $\text{Set}$ its corresponding category of sets and functions, and by $\text{Cat}$ its category of categories and functors, which belongs, of course, to a higher set-theoretic universe.
The most important category-theoretic notions for our work are those of comma category, Grothendieck construction, and generalized subfunctor. We only recall here a number of definitions and elementary properties, mainly for fixing the terminology and the notation to be used throughout the thesis. The interested reader can find more detailed presentations in canonical texts such as [Mac98; AHS09], as well as in works like [GB84; TBG91] on the applications of category theory to algebraic specification.

**Definition 2.1.1** (Comma category). Consider two functors $F_1 : C_1 \to K$ and $F_2 : C_2 \to K$ with the same codomain category $K$. The **comma category** $F_1 / F_2$ is defined as follows:

- the objects are triples $\langle A_1, f, A_2 \rangle$, where $A_1$ is an object of $C_1$, $A_2$ is an object of $C_2$, and $f : F_1(A_1) \to F_2(A_2)$ is an arrow in $K$;
- the arrows $\langle A_1, f, A_2 \rangle \to \langle A'_1, f', A'_2 \rangle$ are pairs $\langle g_1, g_2 \rangle$, where $g_1 : A_1 \to A'_1$ and $g_2 : A_2 \to A'_2$ are arrows in $C_1$ and $C_2$, such that $f \circ F_2(g_2) = F_1(g_1) \circ f'$;
- the composition of arrows is defined componentwise: for every pair of composable arrows $\langle g_1, g_2 \rangle$ and $\langle g'_1, g'_2 \rangle$, $\langle g_1, g_2 \rangle \circ \langle g'_1, g'_2 \rangle = \langle g_1 \circ g'_1, g_2 \circ g'_2 \rangle$.

The comma category $F_1 / F_2$ is often denoted by $C_1 / F_2, F_1 / C_2$, or simply by $C_1 / C_2$ if $F_1, F_2$, or both of them, respectively, correspond to inclusions of categories. A special case arises when $F_1$ is the constant functor with value $A \in |K|$ and $F_2$ is the identity of $K$. Then we denote the comma category $F_1 / F_2$ by $A / K$ – the category of $K$-objects under $A$ – and the forgetful functor $A / K \to K$ that maps every object $\langle A, f, A' \rangle$ of $A / K$ to $A'$ by $\underline{\varepsilon}_A$.

**Fact 2.1.2.** Every arrow $h : A \to A'$ in a given category $K$ induces a left-composition functor $h / K : A' / K \to A / K$ that maps every object $\langle A', f, B \rangle$ of $A' / K$ to $\langle A, h \circ f, B \rangle$ and every arrow $g : \langle A', f_1, B_1 \rangle \to \langle A', f_2, B_2 \rangle$ in $A' / K$ to $g : \langle A, h \circ f_1, B_1 \rangle \to \langle A, h \circ f_2, B_2 \rangle$.

**Definition 2.1.3** (Arrow category). For any category $K$, the **category $K^\rightarrow$ of $K$-arrows** is given by the comma category $1_K / 1_K$.

This means that, intuitively, the objects of the arrow category $K^\rightarrow$ are arrows $f : A_1 \to A_2$ in $K$, and that the morphisms in $K^\rightarrow$ from $f : A_1 \to A_2$ to...
We denote the two canonical projection functors $\mathbb{K}^\to \to \mathbb{K}$ that map the arrows $f: A_1 \to A_2$ in $\mathbb{K}$ (i.e. the objects of $\mathbb{K}^\to$) to their *domain* $A_1$ and *codomain* $A_2$ by $\operatorname{dom}: \mathbb{K}^\to \to \mathbb{K}$ and $\operatorname{cod}: \mathbb{K}^\to \to \mathbb{K}$, respectively.

**Definition 2.1.4** (Indexed category). For any category $\mathcal{I}$ of indices, an $\mathcal{I}$-indexed category is a functor $C: \mathcal{I}^{\to} \to \text{Cat}$.

**Definition 2.1.5** (Grothendieck construction). Any $\mathcal{I}$-indexed category $C: \mathcal{I}^{\to} \to \text{Cat}$ can be ‘flattened’ to a *Grothendieck category* $C^\sharp$ in which

- the *objects* are pairs $\langle i, A \rangle$, where $i$ is an object of $\mathcal{I}$ and $A$ is an object of $C(i)$,
- the *arrows* $\langle i, A \rangle \to \langle i', A' \rangle$ are pairs $\langle u, f \rangle$ such that $u: i \to i'$ is an arrow in $\mathcal{I}$ and $f: A \to C(u)(A')$ is an arrow in $C(i)$, and
- the *composition* of arrows $\langle u, f \rangle$ and $\langle u', f' \rangle$ is defined as $\langle u \circ u', f \circ C(u)(f') \rangle$.

**Fact 2.1.6.** Every indexed functor $F$ between $\mathcal{I}$-indexed categories $C$ and $D: \mathcal{I}^{\to} \to \text{Cat}$, that is every natural transformation $F: C \Rightarrow D$, determines a functor $F^\sharp: C^\sharp \to D^\sharp$ that maps every object $\langle i, A \rangle$ of the Grothendieck category $C^\sharp$ to $\langle i, F_i(A) \rangle$ and every arrow $\langle u, f \rangle: \langle i, A \rangle \to \langle i', A' \rangle$ in $C^\sharp$ to $\langle u, F_i(f) \rangle$. We obtain in this way a ‘flattening’ functor $\_^\sharp$ from the category $[\mathcal{I}^{\to} \to \text{Cat}]$ of $\mathcal{I}$-indexed categories to $\text{Cat}$.

**Definition 2.1.7** (Category of functors). For any category $\mathbb{K}$, the category $[\_ \to \mathbb{K}]^\sharp$ of *functors into* $\mathbb{K}$ is the Grothendieck category defined by the functor $[\_ \to \mathbb{K}]: \text{Cat}^{\to} \to \text{Cat}$ that maps every category $C$ to the category $[C \to \mathbb{K}]$ (with natural transformations as arrows) and any functor $U: C \to C'$ to the left-composition functor $U_\_: [C' \to \mathbb{K}] \to [C \to \mathbb{K}]$.

This means that the objects of $[\_ \to \mathbb{K}]^\sharp$ are, in essence, functors $F: C \to \mathbb{K}$ into the category $\mathbb{K}$, and that the morphisms between two such functors
Thenotionofinstitutionemergedwithinthetheoryofalgebraicspecification.

This means that, for every object $\langle U, \tau \rangle$, where $U$ is a functor $C \to C'$ and $\tau$ is a natural transformation $F \Rightarrow U \circ F'$. Moreover, the composition of morphisms in $\langle \_ \to K \rangle^\sharp$ is defined by $\langle U, \tau \rangle \circ \langle U', \tau' \rangle = \langle U \circ U', \tau \circ (U \cdot \tau') \rangle$.

**Fact 2.1.8**. Functors $G: K \to K'$ determine appropriate natural transformations $[G]$ between $\langle \_ \to K \rangle$ and $\langle \_ \to K' \rangle$; their components $[G]_{\_\_}$, for categories $C \in [\text{Cat}^{\_\_}]$, are the obvious right-composition functors from $[C \to K]$ to $[C \to K']$. Hence, by **Fact 2.1.6**, every functor $G$ between categories $K$ and $K'$ induces a functor $[G]^\sharp: \langle \_ \to K \rangle^\sharp \to \langle \_ \to K' \rangle^\sharp$.

**Definition 2.1.9** (Subfunctor). For any two functors $F, G: C \to \text{Set}$, $F$ is said to be a subfunctor of $G$ (denoted $F \subseteq G$) if there exists a natural transformation $F \Rightarrow G$ whose components are all set-theoretic inclusions.

Therefore, $F$ is a subfunctor of $G$ when for every object $A \in |C|$, $F(A)$ is a subset of $G(A)$, and for every arrow $f: A \to A'$ in $C$, $F(f)$ is the domain-codomain restriction of $G(f)$.

**Definition 2.1.10** (Generalized subfunctor). For any two functors $F, G: I \to [\_ \to \text{Set}]^\sharp$, $F$ is said to be a generalized subfunctor of $G$ (denoted $F \subseteq G$) when $F(i)$ is a natural subfunctor of $G(i)$ for every $i \in |I|$. This means that, for every object $i \in |I|$, $F(i)$ is a subfunctor of $G(i)$ and, for every arrow $u: i \to i'$ in $I$, the $[\_ \to \text{Set}]^\sharp$-morphisms $F(u)$ and $G(u)$ make the following square commute.

\[
\begin{array}{ccc}
i & F(i): C_i \to \text{Set} & G(i): C_i \to \text{Set} \\
\downarrow_{F(u)} & \downarrow^{F(i) \subseteq G(i)} & \downarrow_{G(u)} \\
i' & F(i'): C_{i'} \to \text{Set} & G(i'): C_{i'} \to \text{Set} \end{array}
\]

### 2.2 Institutions

The notion of institution emerged within the theory of algebraic specification from the general concept of language [see BG79]. It was introduced by Goguen and Burstall in [GB92] with the aim of formalizing the intuitive notion of logical system as a balanced interaction between its syntax and its semantics. The theory of institutions provides in this way a rigorous model-theoretic abstraction of logics, and thus it can be used to provide foundations for both specification and programming languages.

In what follows, we recall the basic notions and notations of institutions. Intuitively, an institution consists of a collection (category) of signatures, each of which determines (through dedicated functors) a set of sentences...
and a collection of models, as well as a satisfaction relation between models and sentences that is assumed to be invariant under change of signature.

**Definition 2.2.1 (Institution).** An institution $\mathcal{I}$ consists of

- a category $\text{Sig}^\mathcal{I}$ of signatures and signature morphisms,

- a sentence functor $\text{Sen}^\mathcal{I}: \text{Sig}^\mathcal{I} \to \text{Set}$ defining, for every signature $\Sigma$, the set $\text{Sen}^\mathcal{I}(\Sigma)$ of $\Sigma$-sentences and, for every signature morphism $\varphi: \Sigma \to \Sigma'$, the sentence-translation map $\text{Sen}^\mathcal{I}(\varphi): \text{Sen}^\mathcal{I}(\Sigma) \to \text{Sen}^\mathcal{I}(\Sigma')$,

- a model functor $\text{Mod}^\mathcal{I}: (\text{Sig}^\mathcal{I})^{\text{op}} \to \text{Cat}$ defining, for every signature $\Sigma$, the category $\text{Mod}^\mathcal{I}(\Sigma)$ of $\Sigma$-models and $\Sigma$-(model) homomorphisms and, for every morphism $\varphi: \Sigma \to \Sigma'$, the reduct functor $\text{Mod}^\mathcal{I}(\varphi): \text{Mod}^\mathcal{I}(\Sigma') \to \text{Mod}^\mathcal{I}(\Sigma)$,

- a family of satisfaction relations $\models^\mathcal{I}\subseteq |\text{Mod}^\mathcal{I}(\Sigma)| \times \text{Sen}^\mathcal{I}(\Sigma)$ determining, for every signature $\Sigma$, the satisfaction of $\Sigma$-sentences by $\Sigma$-models,

such that, for any signature morphisms $\varphi: \Sigma \to \Sigma'$, the translation of sentences $\text{Sen}^\mathcal{I}(\varphi)$ and the reduction of models $\text{Mod}^\mathcal{I}(\varphi)$ preserve the satisfaction relation: for every $\Sigma'$-model $M'$ and $\Sigma$-sentence $\rho$,

$$M' \models^\mathcal{I}_\Sigma \text{Sen}^\mathcal{I}(\varphi)(\rho) \quad \text{if and only if} \quad \text{Mod}^\mathcal{I}(\varphi)(M') \models^\mathcal{I}_\Sigma \rho.$$  

This property is usually called the *satisfaction condition* for $\mathcal{I}$.

When there is no danger of confusion, we may omit the superscripts or subscripts from the notations introduced above for the components of institutions. For instance, when the institution $\mathcal{I}$ and the signature $\Sigma$ can be easily inferred, we will often denote the satisfaction relation $\models^\mathcal{I}_\Sigma$ simply by $\models$. In addition, we will frequently denote the sentence translation $\text{Sen}^\mathcal{I}(\varphi)$ by $\varphi(_)\text{ and the reduct functor }\text{Mod}^\mathcal{I}(\varphi)$ by $\_\upharpoonright\varphi$; and we will say that $M$ is the $\varphi$-reduct of $M'$ and that $M'$ is a $\varphi$-expansion of $M$ whenever $M = M' \upharpoonright\varphi$.

Finally, we will use the fact that the satisfaction relation extends in a natural way from sentences to sets of sentences, and we will say that a $\Sigma$-sentence $\rho$ is a semantic consequence of a set of $\Sigma$-sentences $E$, denoted $E \models^\mathcal{I}_\Sigma \rho$, when every $\Sigma$-model that satisfies every sentence in $E$ satisfies $\rho$ as well.

Note that, for any signature $\Sigma$ of an institution $\mathcal{I}$, the satisfaction relation $\models^\mathcal{I}_\Sigma$ can be identified with a Boolean-valued function $\models^\mathcal{I}_\Sigma: \text{Sen}^\mathcal{I}(\Sigma) \to \{0, 1\}$ that determines whether any given $\Sigma$-sentence is satisfied by any given $\Sigma$-model. In view of this observation, the satisfaction condition for $\mathcal{I}$ can be captured categorically by defining the satisfaction relations $\models^\mathcal{I}_\Sigma$ as components of a natural transformation

$$\models^\mathcal{I}: \text{Sen}^\mathcal{I} \Rightarrow [\text{Mod}^\mathcal{I}(\Sigma) \to 2]$$
from $\text{Sen}^3$ to the functor $\langle |\text{Mod}^3(\_)| \to 2 \rangle$ that maps every signature $\Sigma \in |\text{Sig}^3|$ to the collection of all functions from $|\text{Mod}^3(\Sigma)|$ to the two-element set 2.

\[
\begin{array}{ccc}
\Sigma & \xrightarrow{\text{Sen}^3(\Sigma)} & |\text{Mod}^3(\Sigma)| \to 2 \\
\phi & \downarrow & \downarrow \\
\Sigma' & \xrightarrow{\text{Sen}^3(\phi)} & |\text{Mod}^3(\Sigma')| \to 2
\end{array}
\]

A large number of logical systems have been formalized as institutions. Some examples related to the study of logic programming include (many-sorted) first-order logic [see GB92], order-sorted Horn-clause logic with equality [see GM87], category-based equational logic [see Dia95], higher-order logic [see MTW87], hidden algebra [see GMK02], constraint logic [see Dia00], and the rather recent logic of asynchronous relational networks described in [ŢF13]. Many others are thoroughly discussed in monographs on institutions and algebraic specifications such as [Dia08; ST11].

The present thesis is mainly concerned with institutions of substitutions, that is with ‘local’ institutions that are usually defined over a given signature of a logical system such as first-order or higher-order logic, whose signatures are abstract representations of (sets of) variables, and whose signature morphisms correspond to substitutions. These structures provide convenient abstractions of the basic elements involved in defining the denotational and the operational semantics of logic programs. A detailed presentation of the institutions of first-order substitutions is given in Section 3.1.1.

Changing signatures (by means of signature morphisms) yields appropriate maps between their corresponding institutions of substitutions, formalized as institution comorphisms [GR02]. These capture the intuitive notion of embedding simpler logical systems into more complex ones, and are dual to the original concept of institution morphism [GB92], which corresponds to structure-forgetting relationships between logical systems. Institution comorphisms were originally discussed in [Mes89] under the name of plain maps, and in [Tar95] under the name of institution representations.

**Definition 2.2.2** (Comorphism of institutions). For any two institutions $\mathcal{I} = \langle \text{Sig}, \text{Sen}, \text{Mod}, \vDash \rangle$ and $\mathcal{I}' = \langle \text{Sig}', \text{Sen}', \text{Mod}', \vDash' \rangle$, a comorphism $\mathcal{I} \to \mathcal{I}'$ is a triple $\langle \Phi, \alpha, \beta \rangle$ for which

- $\Phi$ is a signature functor $\text{Sig} \to \text{Sig}'$,
- $\alpha$ is a natural transformation $\text{Sen} \Rightarrow \Phi \downarrow \text{Sen}'$, and
- $\beta$ is a natural transformation $\Phi^{\text{op}} \downarrow \text{Mod}' \Rightarrow \text{Mod}$,
such that the following property – the *satisfaction condition* for \( \langle \Phi, \alpha, \beta \rangle \) – holds for every \( I \)-signature \( \Sigma \), \( \Phi(\Sigma) \)-model \( M' \), and \( \Sigma \)-sentence \( \rho \):

\[
M' \models_{\Phi(\Sigma)} \alpha_{\Sigma}(\rho) \quad \text{if and only if} \quad \beta_{\Sigma}(M') \models_{\Sigma} \rho.
\]

Institution comorphisms compose in a natural, componentwise manner. Their composition is associative and has identities, thus providing a category \( \text{coIns} \) of institutions and institution comorphisms.

### 2.3 INSTITUTIONS AS FUNCTORS

Institutions can also be defined as functors into a category of local satisfaction systems called *rooms* or *twisted relations* [see GB02]. This alternative characterization has proved to be convenient for various studies on generalized institutions [see GB86], heterogeneous logical systems [see Mos02; Mos06], and logic translations [see MDT09].

**Definition 2.3.1** (Rooms and corridors). The category \( \text{Room} \) of *rooms* and *corridors* is defined as follows:

The *objects* are *Boolean rooms*, that is triples \( \langle S, \mathbb{M}, \models \rangle \) consisting of

- a set \( S \) of *sentences*,
- a category \( \mathbb{M} \) of *models*, and
- a *satisfaction relation* \( \models \subseteq |\mathbb{M}| \times S \).

The *morphisms* – *corridors* – \( \langle S, \mathbb{M}, \models \rangle \to \langle S', \mathbb{M}', \models' \rangle \) are pairs \( \langle \alpha, \beta \rangle \), where

- \( \alpha \) is a *sentence-translation function* \( S \to S' \) and
- \( \beta \) is a *model-reduction functor* \( \mathbb{M}' \to \mathbb{M} \),

such that the following condition holds for all \( M' \in |\mathbb{M}'| \) and \( \rho \in S \):

\[
M' \models' \alpha(\rho) \quad \text{if and only if} \quad \beta(M') \models \rho.
\]

The *composition* of morphisms is defined componentwise.

The ternary structure of rooms induces appropriate projections \( \text{Sen} \) and \( \text{Mod} \) into the categories of sets and categories, respectively, as well as a natural transformation \( \models \) that captures the invariance of the satisfaction of sentences by models with respect to the change of rooms:

---

1. For simplicity, we overload the use of \( \text{Sen} \), \( \text{Mod} \), and \( \models \). To resolve the potential confusion between the projections of \( \text{Room} \) and the sentence functor, model functor, and satisfaction relations of an institution \( \mathcal{I} \), we usually denote the latter by \( \text{Sen}^\mathcal{I} \), \( \text{Mod}^\mathcal{I} \), and \( \models^\mathcal{I} \), respectively.
- \text{Sen}: \text{Room} \to \text{Set} \text{ and } \text{Mod}: \text{Room}^{\text{op}} \to \text{Cat} \text{ are the functors that map every room } \langle S, M, \vDash \rangle \text{ to its underlying set of sentences } S \text{ and category of models } M \text{ respectively, and }
- \vDash \text{ is the natural transformation } \text{Sen} \Rightarrow [\text{Mod}(\_)] \to 2 \text{ whose components are given by the satisfaction relations of the considered rooms.}

Hence, \text{Room} \text{ can also be understood as the comma category } \text{Set} / [\_] \to 2.

\textbf{Fact 2.3.2.} The categories } \text{Room} \text{ and } \text{Set} / [\_] \to 2 \text{ are isomorphic.

The observation above allows us to identify every institution } I \text{ having } \text{Sig} \text{ as the category of signatures with the functor } I: \text{Sig} \to \text{Room} \text{ that maps }
- \text{every signature } \Sigma \text{ to } \langle \text{Sen}^I(\Sigma), \text{Mod}^I(\Sigma), \vDash^I_\Sigma \rangle \text{ and }
- \text{every signature morphism } \varphi \text{ to } \langle \text{Sen}^I(\varphi), \text{Mod}^I(\varphi) \rangle.

Conversely, every functor } I: \text{Sig} \to \text{Room} \text{ describes an institution whose category of signatures, sentence functor, model functor, and family of satisfaction relations are given by } \text{Sig}, I \circ \text{Sen}, I^{\text{op}} \circ \text{Mod}, \text{ and } I \cdot \vDash \text{ respectively.}

This one-to-one correspondence between institutions and functors into \text{Room} \text{ can be easily extended to maps of institutions: every comorphism of institutions } \langle \Phi, \alpha, \beta \rangle : I \to I' \text{ can be regarded as an arrow } \langle \Phi, \tau \rangle \text{ between the functors } I: \text{Sig} \to \text{Room} \text{ and } I': \text{Sig} \to \text{Room}, \text{ where, for every } I\text{-signature } \Sigma, \tau_\Sigma \text{ is the corridor } \langle \alpha_\Sigma, \beta_\Sigma \rangle; \text{ in the opposite direction, } \alpha \text{ and } \beta \text{ can be derived from the 'horizontal' compositions } \tau \circ \text{Sen} \text{ and } \tau^{\text{op}} \circ \text{Mod} \text{ respectively.}

\textbf{Fact 2.3.3.} The categories } \text{collIns} \text{ and } [\_ \to \text{Room}]^\# \text{ are isomorphic.
INTRODUCING LOGIC-INDEPENDENT LOGIC PROGRAMMING

Following the work of Goguen and Burstall, in this chapter we propose a logic-independent approach to logic programming through which the paradigm as we know it for Horn-clause logic can be systematically examined for other formalisms. For this purpose, we introduce an abstract concept of generalized substitution system that extends institutions by allowing for direct representations of variables and substitutions, providing in this way support for the development of both the denotational and the operational semantics of logic programming. In this framework, we study a logic-independent variant of Herbrand’s theorem and describe a general resolution-based procedure for computing solutions to queries. We prove that this procedure is sound and that, moreover, under additional hypotheses that reflect faithfully properties of actual logic-programming languages, it is also complete.

3.1 THE LOGICAL SYSTEM OF REFERENCE

Our first step towards a presentation of the foundations of logic programming that does not depend on any concrete logical system consists in determining an appropriate benchmark institution that will enable us to relate to concepts and results specific to conventional logic programming [see generally Llo87]. To this end, we recall that logic programming has been traditionally studied in the Horn subinstitution of $\text{FOL}_1^1$ – the single-sorted variant of first-order logic without equality.

SIGNATURES. A $\text{FOL}_1^1$-signature is a pair $\langle F, P \rangle$ where $F$ and $P$ are $\omega$-indexed families $(F_n)_{n \in \omega}$ and $(P_n)_{n \in \omega}$ of disjoint sets of operation and relation symbols respectively. The indices are usually called arities and qualify the operation and relation symbols; in this sense, we denote an operation or relation symbol $\varsigma$ of arity $n$ by $\varsigma : n$. However, when there is no risk of confusion, we may drop the additional qualification and denote $\varsigma : n$ simply by $\varsigma$. 
The signature morphisms $\varphi: \langle F, P \rangle \rightarrow \langle F', P' \rangle$ reflect the structure of signatures and consist of families $\varphi^{\text{op}}$ and $\varphi^{\text{rel}}$ of functions $\varphi_n^{\text{op}}: F_n \rightarrow F'_n$ and $\varphi_n^{\text{rel}}: P_n \rightarrow P'_n$, for $n \in \omega$, between the corresponding sets of operation and relation symbols, respectively.

**SENTENCES.** The sentences are ordinary first-order sentences built over relational atoms for convenience, we assume that disjunctions, denoted $\lor$, corresponding to the signature which allows us to define the translation of relational atoms $\pi(t_1, \ldots, t_n)$ are defined over arbitrary finite sets of sentences $E$, and we abbreviate $\land \{p_1, p_2\}$ as $p_1 \land p_2$ and $\land \emptyset$ as true. When there is no danger of confusion, we may also abbreviate $\land \{p\}$ as $p$.

The translation of universally quantified sentences along a signature morphism $\varphi: \langle F, P \rangle \rightarrow \langle F', P' \rangle$ is defined inductively on the structure of sentences by replacing the symbols of $\langle F, P \rangle$ according to $\varphi$. To be more precise, $\varphi$ determines a function $\varphi^{\text{lm}}: T_F \rightarrow T_{F'}$ given by $\sigma(t_1, \ldots, t_n) \mapsto \varphi_n^{\text{op}}(\sigma)(\varphi_{t_1}^{\text{lm}}(t_1), \ldots, \varphi_{t_n}^{\text{lm}}(t_n))$, which allows us to define the translation of relational atoms $\pi(t_1, \ldots, t_n)$ – corresponding to the signature $\langle F, P \rangle$ – as $\varphi_n^{\text{rel}}(\pi)(\varphi_{t_1}^{\text{lm}}(t_1), \ldots, \varphi_{t_n}^{\text{lm}}(t_n))$.

This definition can be straightforwardly extended to more complex sentences. For instance, the translation of universally quantified $\langle F, P \rangle$-sentences is given by $\forall X \cdot \rho \mapsto \forall X^\varphi \cdot \varphi^X(\rho)$, where $X^\varphi$ is the set of $\langle F', P' \rangle$-variables $\{ (x, F_0^\varphi) \mid (x, F_0) \in X \}$ and $\varphi^X: \langle F \cup X, P \rangle \rightarrow \langle F' \cup X^\varphi, P' \rangle$ is the canonical extension of $\varphi$ such that $(\varphi^X)^{\text{op}}(x, F_0^\varphi) = (x, F'_0)$ for every $(x, F_0) \in X$.

**MODELS.** Given a $\text{FOL}_x^1$-signature $\langle F, P \rangle$, an $\langle F, P \rangle$-model $M$ consists of

- a set $|M|$, called the carrier set of $M$, together with
- a function $M_\sigma: |M|^n \rightarrow |M|$ for each operation symbol $\sigma \in F_n$ and
- a subset $M_\pi \subseteq |M|^n$ for each relation symbol $\pi \in P_n$.  

---

\[\begin{array}{c}
\langle F, P \rangle \xrightarrow{\varphi} \langle F', P' \rangle \\
\subseteq \\
\langle F \cup X, P \rangle \xrightarrow{\varphi^X} \langle F' \cup X^\varphi, P' \rangle
\end{array}\]
Homomorphisms $h: M_1 \to M_2$ are functions $h: |M_1| \to |M_2|$ between the carrier sets of $M_1$ and $M_2$ satisfying the following two properties:

1. Preservation of operations: $h(M_1,\sigma(m_1,\ldots,m_n)) = M_2,\sigma(h(m_1),\ldots,h(m_n))$ for all operation symbols $\sigma \in F_\sigma$ and all arguments $m_1,\ldots,m_n \in |M_1|$.

2. Preservation of relations: $h(M_1,\pi) \subseteq M_2,\pi$ for all relation symbols $\pi \in P_\pi$.

Concerning model reducts, for any signature morphism $\varphi: \langle F, P \rangle \to \langle F', P' \rangle$ and $\langle F', P' \rangle$-model $M'$, the $\varphi$-reduct $M'\upharpoonright_\varphi$ is defined as the $\langle F, P \rangle$-model $M$ with the same carrier set as $M'$ and with the interpretation of operation and relation symbols given by $M_\varphi = M'_{\varphi(\cdot)}$ for every symbol $\cdot$ in $\langle F, P \rangle$.

**The Satisfaction Relation.** The *satisfaction* between models and sentences is the usual Tarskian satisfaction defined inductively on the structure of sentences and based on the evaluation of terms in models. For example, an $\langle F, P \rangle$-model $M$ satisfies a universally quantified $\langle F, P \rangle$-sentence $\forall X \cdot \rho$ if all of its expansions along the signature inclusion $\langle F, P \rangle \subseteq \langle F \cup X, P \rangle$ satisfy $\rho$; thus, $M \vDash_{\langle F, P \rangle} \forall X \cdot \rho$ if $N \vDash_{\langle F \cup X, P \rangle} \rho$ for all models $N$ of $\langle F \cup X, P \rangle$ such that $N \upharpoonright_{\langle F, P \rangle} = M$, that is for all valuations in $M$ of the variables in $X$.

The approach that we follow in the present inquiry on the foundations of logic programming relies on abstract concepts of universally and existentially quantified sentences, whose definitions are independent of the logical system of choice. For this reason, our description of conventional logic programming is not based on the institution $\text{FOL}^1$ discussed above, but on its quantifier-free fragment (with sentences built from atoms by repeated applications of Boolean connectives), which we denote by $\text{qFOL}^1_{\varepsilon}$.

### 3.1.1 Institutions of Substitutions

**The Category of Substitutions.** Let us fix a $\text{qFOL}^1_{\varepsilon}$-signature $\langle F, P \rangle$, for example the following signature of natural numbers with addition (specified as a ternary predicate): $F_{\text{nat}} = \{ 0, \text{ s } \colon 1 \}$, $P_{\text{nat}} = \{ \text{add } 3 \}$.

In this setting, variables (or, more precisely, sets of variables) can be seen as signatures of a specialized logical system. A *signature of variables* is just a set $X$ of $\langle F, P \rangle$-variables with distinct names, which, by definition, shares no elements with the set $F_0$ of constant-operation symbols. The syntactic entities over a given signature of variables $X$ are defined as the corresponding $\text{qFOL}^1_{\varepsilon}$-expressions that can be formed based on the operation and relation symbols of $\langle F, P \rangle$ and on the variables of $X$ considered as new constants. For example, the terms over $X$, or with variables from $X$, can be informally defined in an inductive manner as follows:
every variable of $X$ is a term over $X$ and

for every arity $n$, if $\sigma$ is an operation symbol in $F_n$ and $t_1, \ldots, t_n$ are terms over $X$, then $\sigma(t_1, \ldots, t_n)$ is a term over $X$ as well.

Substitutions provide syntactic transformations on expressions that are defined over sets of variables: given two signatures of variables $X$ and $Y$, a substitution $\psi: X \rightarrow Y$ is a map $\psi: X \rightarrow T_{FU}$ that associates a term over $Y$ with every variable of $X$. Note that any substitution $\psi: X \rightarrow Y$ can be canonically extended to a function $\psi^\text{im}: T_{FU} \rightarrow T_{FU}$ defined by $x \mapsto \psi(x)$ for variables, and by $\sigma(t_1, \ldots, t_n) \mapsto \sigma(\psi^\text{im}(t_1), \ldots, \psi^\text{im}(t_n))$ for compound terms. This allows us to define the composition of substitutions $\psi: X \rightarrow Y$ and $\theta: Y \rightarrow Z$ as the map $\psi \circ \theta^\text{im}: X \rightarrow T_{FU}$. It is easy to see that $\psi \circ \theta$ induces the term translation $\psi^\text{im} \circ \theta^\text{im}$, which entails that the composition of substitutions is associative. Moreover, it satisfies the identity laws by taking, for every signature of variables $X$, the identity $1_X$ as the function that encodes the variables of $X$ as terms over $X$. Hence, the signatures of $(F, P)$-variables together with their corresponding substitutions form a category $\text{Subst}_{(F, P)}$.

**Sentences, Models, and the Satisfaction Relation.** Signatures of variables do not inherit only the terms of the extended $\mathfrak{QFOL}_2$-signatures, but also their sentences, models, and the satisfaction relation between them. For every signature of variables $X$ we define

- the set of sentences $\text{Sen}_{(F, P)}(X)$ as $\text{Sen}(F \cup X, P)$,
- the category of models $\text{Mod}_{(F, P)}(X)$ as $\text{Mod}(F \cup X, P)$, and
- the satisfaction relation $\vDash_{(F, P), X}$ as $\vDash_{(F \cup X, P)}$.

With respect to substitutions, notice that, for every two signatures of variables $X$ and $Y$, every substitution $\psi: X \rightarrow Y$ determines

- a sentence-translation map $\text{Sen}_{(F, P)}(\psi): \text{Sen}_{(F, P)}(X) \rightarrow \text{Sen}_{(F, P)}(Y)$ defined on atomic sentences by $\pi(t_1, \ldots, t_n) \mapsto \pi(\psi^\text{im}(t_1), \ldots, \psi^\text{im}(t_n))$, and
- a model-reduct functor $\text{Mod}_{(F, P)}(\psi): \text{Mod}_{(F, P)}(Y) \rightarrow \text{Mod}_{(F, P)}(X)$ that maps every $Y$-model $N$ to the $X$-model $N \upharpoonright_\psi$ given by $|N \upharpoonright_\psi| = |N|$, $(N \upharpoonright_\psi)_c = N_c$ for each symbol $c$ of $(F, P)$, and $(N \upharpoonright_\psi)_x = N_{\psi(x)}$ (the evaluation of the term $\psi(x)$ in $N$) for each variable $x$ in $X$.

We have thus defined the four components of an institution of $(F, P)$-substitutions: the category $\text{Subst}_{(F, P)}$ of signatures (of variables) and signature morphisms (substitutions), the sentence functor $\text{Sen}_{(F, P)}: \text{Subst}_{(F, P)} \rightarrow \text{Set}$, the model functor $\text{Mod}_{(F, P)}: \text{Subst}_{(F, P)} \rightarrow \text{Cat}$, and the family of satisfaction
relations \((\varphi(F,P),X)_{X \in [\text{Subst}(F,P)]}\).

Our construction is completed by the following result, originally discussed in [Dia04], which states that satisfaction is invariant under substitution of variables.

**Proposition 3.1.1.** For every first-order substitution \(\psi: X \rightarrow Y\), every model \(N\) of \(Y\), and every sentence \(\rho\) with variables from \(X\),

\[ N \models_{(F,P),Y} \text{Sen}_{(F,P)}(\psi)(\rho) \quad \text{if and only if} \quad \text{Mod}_{(F,P)}(\psi)(N) \models_{(F,P),X} \rho. \]

\(\square\)

**Corollary 3.1.2.** For every \(\text{FOL}_1\)-signature \(\langle F, P \rangle\), the structure

\[ (\text{FOL}_1)_{\langle F, P \rangle} = (\text{Subst}_{(F,P)}, \text{Sen}_{(F,P)}, \text{Mod}_{(F,P)}, \models_{(F,P)}) \]

defines an institution – the institution of \(\langle F, P \rangle\)-substitutions.

\(\square\)

The institutions of substitutions are not considered in isolation; instead, they are linked by various institution comorphisms induced by morphisms between their underlying first-order signatures.

**Proposition 3.1.3.** Every \(\text{FOL}_1\)-signature-morphism \(\varphi: \langle F, P \rangle \rightarrow \langle F', P' \rangle\) determines a comorphism \(\langle \Psi_{\varphi}, \alpha_{\varphi}, \beta_{\varphi} \rangle\) between the institutions of \(\langle F, P \rangle\)- and \(\langle F', P' \rangle\)-substitutions, where

- \(\Psi_{\varphi}(X) = X^\varphi\) and \(\Psi_{\varphi}(\psi)(x, F'_0) = (\varphi^Y)^{\text{im}}(\psi(x, F_0))\),
- \(\alpha_{\varphi,X} = \text{Sen}(\varphi^X)\), and
- \(\beta_{\varphi,X} = \text{Mod}(\varphi^X)\),

for each signature of \(\langle F, P \rangle\)-variables \(X\), \(\langle F, P \rangle\)-substitution \(\psi: X \rightarrow Y\), and variable \((x, F'_0) \in X^\varphi\).

**Proof.** We begin by proving that \(\Psi_{\varphi}\) is a functor \(\text{Subst}_{(F,P)} \rightarrow \text{Subst}_{(F',P')}\). Following an inductive argument on the structure of terms, we can easily infer that, for every \(\langle F, P \rangle\)-substitution \(\psi: X \rightarrow Y\), the translations \((\varphi^X)^{\text{im}} \downarrow \Psi_{\varphi}(\psi)^{\text{im}}\) and \(\psi^{\text{im}} \downarrow (\varphi^Y)^{\text{im}}\) (of \(F\)-terms over \(X\) into \(F'\)-terms over \(Y^\varphi\)) are equal. Based on this property, for any pair of composable \(\langle F, P \rangle\)-substitutions \(\psi: X \rightarrow Y\) and \(\theta: Y \rightarrow Z\), we obtain the following chain of equalities:

\[
\Psi_{\varphi}(\psi \downarrow \theta)(x, F_0)
= (\varphi^Z)^{\text{im}}((\psi \downarrow \theta)(x, F_0)) \quad \text{by the definition of } \Psi_{\varphi}(\psi \downarrow \theta)
= (\varphi^Z)^{\text{im}}(\theta^{\text{im}}(\psi(x, F_0))) \quad \text{according to the definition of composition in } \text{Subst}_{(F,P)}
\]
The institutions of substitutions discussed in Section 3.1 provide the most basic building blocks needed for writing logic programs: signatures of variables and sentences over those signatures. For instance, the following definition of the addition of natural numbers (which makes use of the dedicated clausal notation specific to logic programming)

\[
\begin{align*}
\text{add}(\theta, M, M) & \leftarrow M \\
\text{add}(s \, M, N, s \, P) & \leftarrow_{M, N, P} \text{add}(M, N, P)
\end{align*}
\]

can be presented formally as the set given by the universal closures of the sentences \( \text{true} \not\Rightarrow \text{add}(\theta, M, M) \) and \( \text{add}(M, N, P) \not\Rightarrow \text{add}(s \, M, N, s \, P) \) defined
over the signatures of \( \langle F_{\text{nat}}, P_{\text{nat}} \rangle \)-variables \( \{M\} \) and \( \{M, N, P\} \), respectively.

In order to describe the semantics of such definitions at the same level of abstraction, we need to make explicit the translations of sentences and the reductions of models that correspond to signature extensions such as \( \langle F_{\text{nat}}, P_{\text{nat}} \rangle \subseteq \langle F_{\text{nat}} \cup \{M\}, P_{\text{nat}} \rangle \). A possible approach is to consider signatures of \( \Sigma \)-variables, for some signature \( \Sigma \) of a given logical system, as specific morphisms \( X : \Sigma \to \Sigma(X) \). This treatment of (signatures of) variables was first outlined in [ST84] as part of an institutional approach to open formulae, and is related to many developments in institution theory such as institution-independent semantics for quantifiers [Tar86], ultraproducts [Dia08], general versions of Herbrand theorems [Dia04], Birkhoff completeness [CG08], hybridization [Mar+11], structural induction [Dia11], constructor-based logics [GFO12], and forcing techniques [GP10; Găi14].

The framework that we propose for formalizing signatures of variables (and substitutions) generalizes the aforementioned approach by taking into account only their corresponding extensions of rooms. This choice is motivated by the difficulties that may arise in defining variables as signature extensions in other logical systems of interest for logic programming, such as the institution of asynchronous relational networks [see TF13]. In that case, signatures (and, consequently, signature morphisms) and variables are significantly different from a structural point of view: the former are logical systems satisfying given properties, while the latter are hypergraphs whose vertices and hyperedges are labelled with signatures and models of their underlying logical system; for this reason, variables cannot be faithfully represented through extensions of their base signatures.

**Definition 3.2.1** (Substitution system). A substitution system is a triple \((\text{Subst}, G, S)\), usually denoted simply by \(S\), consisting of

- a category \(\text{Subst}\) of signatures of variables and substitutions,
- a room \(G\) of ground sentences and models, and
- a functor \(S : \text{Subst} \to G / \text{Room}\) defining, for every signature of variables \(X\), the corridor \(S(X) : G \to G(X)\) to the room \(G(X)\) of \(X\)-sentences and \(X\)-models.

Therefore, given a room \(G = (\text{Sen}(G), \text{Mod}(G), \Vdash_G)\) of ground sentences and models, the signatures of variables are defined abstractly as objects \(X\) of a category \(\text{Subst}\) for which we consider (a) a set \(\text{Sen}(G(X))\) of \(X\)-sentences together with a sentence-extension map \(\alpha_X : \text{Sen}(G) \to \text{Sen}(G(X))\), (b) a category \(\text{Mod}(G(X))\) of \(X\)-models together with a model-reduction functor \(\beta_X : \text{Mod}(G(X)) \to \text{Mod}(G)\), and (c) a satisfaction relation \(\Vdash_{G(X)}\) between
X-models and X-sentences such that the following satisfaction condition holds for all X-models N and ground sentences ρ:

\[ N \vDash_{G(X)} \alpha_X(\rho) \quad \text{if and only if} \quad \beta_X(N) \vDash \rho. \]

Similarly, substitutions ψ: X → Y are arrows in Subst for which we consider (a) a sentence-translation map Sen(ψ): Sen(G(X)) → Sen(G(Y)) and (b) a model-reduction functor Mod(ψ): Mod(G(Y)) → Mod(G(X)) such that the following diagrams commute

\[
\begin{array}{ccc}
Sen(G(X)) & \xrightarrow{\alpha_Y} & Sen(G(Y)) \\
\downarrow{\text{Sen}(\psi)} & & \downarrow{\text{Sen}(\psi)} \\
Mod(G(X)) & \xrightarrow{\beta_Y} & Mod(G(Y))
\end{array}
\]

and, for every Y-model N and X-sentence ρ,

\[ N \vDash_{G(Y)} \text{Sen}(\psi)(\rho) \quad \text{if and only if} \quad \text{Mod}(\psi)(N) \vDash_{G(X)} \rho. \]

It should be noted that, whenever the signatures of variables are defined as extensions of their base signatures (in a given institution), the corridors \( \langle \text{Sen}(\psi), \text{Mod}(\psi) \rangle \) determined by substitutions \( \psi: X \to Y \) correspond to the institution-independent concept of substitution defined in [Dia94]. A detailed presentation of this approach is given in Section 4.2.

**Example 3.2.2.** Every \( \text{qr-FOL}^1 \)-signature \( \langle F, P \rangle \) gives rise to a substitution system \( \langle \text{qr-FOL}^1 \rangle_{\langle F, P \rangle}: \text{Subst}_{\langle F, P \rangle} \to \text{qr-FOL}^1_{\langle F, P \rangle} / \text{Room}^2 \) in which

- signatures of \( \langle F, P \rangle \)-variables X determine corridors given by set-theoretic inclusions \( \text{Sen}(F, P) \subseteq \text{Sen}_{\langle F, P \rangle}(X) \) and model-reduct functors \( \text{Mod}_{\langle F, P \rangle}(X) \to \text{Mod}(F, P) \) that forget the interpretation of variables, and
- substitutions \( \psi: X \to Y \) are mapped to \( \langle \text{Sen}_{\langle F, P \rangle}((\psi)), \text{Mod}_{\langle F, P \rangle}((\psi)) \rangle \).

Note that we can easily recover the institution of \( \langle F, P \rangle \)-substitutions described in Corollary 3.1.2 (regarded as a functor into \text{IRoom}) by means of a straightforward composition:

\[ \langle \text{qr-FOL}^1 \rangle_{\langle F, P \rangle} = \langle \text{qr-FOL}^1 \rangle_{\langle F, P \rangle} \upharpoonright_{\text{qr-FOL}^1_{\langle F, P \rangle}}. \]

Working with substitution systems instead of the simpler institutions of

\[ \text{In this case, the room } \text{qr-FOL}^1_{\langle F, P \rangle} \text{ is just the image of the first-order signature } \langle F, P \rangle \text{ under the functor representation of the institution qr-FOL}^1_{\langle F, P \rangle}. \]
substitutions means that we also need to consider an adequate notion of map of substitution systems.

**Definition 3.2.3** (Morphism of substitution systems). A morphism between substitution systems \( S : \text{Subst} \rightarrow G / \text{Room} \) and \( S' : \text{Subst}' \rightarrow G' / \text{Room} \) is a triple \( \langle \Psi, \kappa, \tau \rangle \), where

\[
\begin{array}{ccc}
\text{Subst} & \xrightarrow{S} & G / \text{Room} \\
\downarrow{\Psi} & & \downarrow{\kappa / \text{Room}} \\
\text{Subst}' & \xrightarrow{S'} & G' / \text{Room}
\end{array}
\]

- \( \Psi \) is a functor \( \text{Subst} \rightarrow \text{Subst}' \),
- \( \kappa \) is a corridor \( G \rightarrow G' \), and
- \( \tau \) is a natural transformation \( S \Rightarrow \Psi \circ S' \) (\( \kappa / \text{Room} \)).

**Proposition 3.2.4.** For every morphism of \( \text{QF-FOL}^1_x \)-signatures \( \varphi : \langle F, P \rangle \rightarrow \langle F', P' \rangle \), the comorphism \( \langle \Psi \varphi, \alpha \varphi, \beta \varphi \rangle \) given in Proposition 3.1.3 can be extended to a morphism of substitution systems

\[
\langle \Psi \varphi, \kappa \varphi, \tau \varphi \rangle : (\text{QF-FOL}^1_x)_{\langle F, P \rangle} \rightarrow (\text{QF-FOL}^1_x)_{\langle F', P' \rangle}
\]

where \( \kappa \varphi \) is the corridor \( \text{QF-FOL}^1_x(\varphi) = (\text{Sen}(\varphi), \text{Mod}(\varphi)) \) and, for every signature of \( \langle F, P \rangle \)-variables \( X \), \( \tau \varphi, X = \langle \alpha \varphi, X, \beta \varphi, X \rangle \).

**Proof.** All we need to check is that, for every signature of \( \langle F, P \rangle \)-variables \( X \), \( \tau \varphi, X \) is indeed an arrow in the comma category \( \text{QF-FOL}^1_x(\langle F, P \rangle) / \text{Room} \). This follows directly from the fact that the equality

\[
(\text{QF-FOL}^1_x)_{\langle F, P \rangle}(X) \triangleright \tau \varphi, X = \kappa \varphi \triangleright (\text{QF-FOL}^1_x)_{\langle F', P' \rangle}(\Psi \varphi(X))
\]

can be obtained by applying the functor \( \text{QF-FOL}^1_x : \text{Sig}^{\text{QF-FOL}^1_x} \rightarrow \text{Room} \) to the commutative diagram below.

\[
\begin{array}{ccc}
\langle F, P \rangle & \xrightarrow{\varphi} & \langle F', P' \rangle \\
\downarrow{2} & & \downarrow{2} \\
\langle F \cup X, P \rangle & \xrightarrow{\varphi \times} & \langle F' \cup X \varphi, P' \rangle
\end{array}
\]

As expected, the composition of morphisms of substitution systems can be straightforwardly defined in terms of their components: for any two morphisms \( \langle \Psi, \kappa, \tau \rangle : S \rightarrow S' \) and \( \langle \Psi', \kappa', \tau' \rangle : S' \rightarrow S'' \) between substitution
systems \( S : \text{Subst} \to G / \text{Room} \), \( S' : \text{Subst} \to G' / \text{Room} \), and \( S'' : \text{Subst}'' \to G'' / \text{Room} \), and \( \langle \Psi, \kappa, \tau \rangle \) \( \in \langle \Psi', \kappa', \tau' \rangle : S \to S'' \) is given by

- the translation of signatures of variables \( \Psi : \text{Subst} \to \text{Subst}'' \),
- the translation of ground sentences and models \( \kappa : G \to G'' \), and
- the translation of sentences and models defined over signatures of variables

\[
\tau \circ (\Psi \cdot \tau' \cdot (\kappa / \text{Room})): S \Rightarrow (\Psi \cdot \tau') \circ S'' \circ (\kappa \circ \kappa'/ \text{Room}),
\]

where, for every \( X \in \text{Subst} \), \( (\tau \circ (\Psi \cdot \tau' \cdot (\kappa / \text{Room}))))_X = \tau_X \circ \tau'_{\Psi(X)} \).

Together with the obvious identities, the construction above yields a category \( \text{SubstSys} \) with substitution systems as objects and morphisms of substitution systems as arrows.

**Fact 3.2.5.** The category \( \text{SubstSys} \) arises from the Grothendieck construction for the functor \( [-, -] / \text{Room} : (\text{Cat} \times \text{Room})^{op} \to \text{Cat} \) that maps

- every category \( \text{Subst} \) and room \( G \) to \( \text{Subst} \to G / \text{Room} \), the category of functors from \( \text{Subst} \) to \( G / \text{Room} \), and
- every functor \( \Psi : \text{Subst} \to \text{Subst}' \) and corridor \( \kappa : G \to G' \) to the composition functor \( \Psi \circ (\kappa / \text{Room}) : \text{Subst}' \to G' / \text{Room} \to \text{Subst} \to G / \text{Room} \).

We conclude the present section by noticing that the construction of first-order substitution systems is functorial, in the sense that it can be described as a functor into \( \text{SubstSys} \) (see Example 3.2.2 and Proposition 3.2.4). We can thus define the following concept of generalized substitution system.

**Definition 3.2.6** (Generalized substitution system). Generalized substitution systems are objects of the category \( [-, \text{SubstSys}] \) of functors into \( \text{SubstSys} \).

Therefore, generalized substitution systems are functors \( \mathcal{S} : \text{Sig} \to \text{SubstSys} \) from a category \( \text{Sig} \) of signatures and signature morphisms to \( \text{SubstSys} \). Because this definition is rather compact and lacks some of the transparency needed for dealing with logic-programming languages, let us first establish the notations and terminology that we will use throughout our work.

- Given a signature \( \Sigma \) of a generalized substitution system \( \mathcal{S} \), we will denote the (local) substitution system \( \mathcal{S}(\Sigma) \) by \( \mathcal{S}_\Sigma : \text{Subst}_\Sigma \to G_\Sigma / \text{Room} \), and we will refer to the objects and morphisms of the category \( \text{Subst}_\Sigma \) as signatures of \( \Sigma \)-variables and \( \Sigma \)-substitutions, respectively.\(^3\)

\(^3\)In this regard, generalized substitution systems are similar to the context institutions of [Paw95], which enrich the structure of institutions with explicit notions of context (in place of signatures of variables) and substitution; the latter, however, are concrete, in the sense that the category of models of every signature is concrete over the category of indexed sets.
The room $G_\Sigma$ consists of the set $\text{Sen}(\Sigma)$ of ground $\Sigma$-sentences, the category $\text{Mod}(\Sigma)$ of $\Sigma$-models, and the $\Sigma$-satisfaction relation $\models_\Sigma \subseteq |\text{Mod}(\Sigma)| \times \text{Sen}(\Sigma)$.

- On objects, the functor $\mathcal{G}_\Sigma$ maps every signature of $\Sigma$-variables $X$ to the corridor $\mathcal{G}_\Sigma(X) = \langle \alpha_{\Sigma,X}, \beta_{\Sigma,X} \rangle$ from $G_\Sigma$ to the room $G_\Sigma(X)$, whose set of $X$-sentences, category of $X$-models, and $X$-satisfaction relation are denoted by $\text{Sen}_\Sigma(X)$, $\text{Mod}_\Sigma(X)$, and $\models_{\Sigma,X}$, respectively.

$$\alpha_{\Sigma,X} : \text{Sen}(\Sigma) \rightarrow \text{Sen}_\Sigma(X) \quad \beta_{\Sigma,X} : \text{Mod}(\Sigma) \rightarrow \text{Mod}_\Sigma(X)$$

- On morphisms, $\mathcal{G}_\Sigma$ maps every $\Sigma$-substitution $\psi : X \rightarrow Y$ to the corridor $\mathcal{G}_\Sigma(\psi) = \langle \text{Sen}_\Sigma(\psi), \text{Mod}_\Sigma(\psi) \rangle$ from $G_\Sigma(X)$ to $G_\Sigma(Y)$, which satisfies, by definition, the equality $\mathcal{G}_\Sigma(X) ; \mathcal{G}_\Sigma(\psi) = \mathcal{G}_\Sigma(Y)$.

- With respect to signature morphisms, every arrow $\varphi : \Sigma \rightarrow \Sigma'$ in $\text{Sig}$ determines a morphism of substitution systems $\mathcal{G}_\varphi = \langle \Psi_\varphi, \kappa_\varphi, \tau_\varphi \rangle$ from $\mathcal{G}_\Sigma$ to $\mathcal{G}_{\Sigma'}$, where $\kappa_\varphi$ is the corridor $\langle \text{Sen}(\varphi), \text{Mod}(\varphi) \rangle$ between $G_\Sigma$ and $G_{\Sigma'}$ and, for every signature of $\Sigma$-variables $X$, $\tau_{\varphi,X}$ is the corridor $\langle \alpha_{\varphi,X}, \beta_{\varphi,X} \rangle$ between $G_\Sigma(X)$ and $G_{\Sigma'}(\Psi_\varphi(X))$.

In addition, we adopt similar notational conventions as in the case of institutions. For example, we may use superscripts as in $\text{Subst}_{\Sigma}^{\mathcal{G}}$ in order to avoid potential ambiguities; or we may drop the subscripts of $\models_{\Sigma,X}$ when there is no danger of confusion. Likewise, we will often denote the functions $\text{Sen}(\varphi)$, $\alpha_{\Sigma,X}$, and $\text{Sen}_\Sigma(\psi)$ by $\varphi(\_)$, $X(\_)$, and $\psi(\_)$, respectively, and the functors $\text{Mod}(\varphi)$, $\beta_{\Sigma,X}$, and $\text{Mod}_\Sigma(\psi)$ by $\downarrow \upharpoonright_{\varphi}$, $\uparrow_{\Sigma}$, and $\downarrow \upharpoonright_{\psi}$.

**Example 3.2.7.** The quantifier-free, single-sorted fragment of first-order logic without equality forms a generalized substitution system, which we denote by $\text{qf-FOL}_1^\Sigma$.

$$\text{qf-FOL}_1^\Sigma : \text{Sig}^{\text{qf-FOL}_1} \rightarrow \text{SubstSys}$$
3.2.1 QUANTIFIED SENTENCES

The last ingredient needed to interpret logic programs is an appropriate concept of quantified sentence over a given generalized substitution system. To this purpose, we introduce universal and existential closures of sentences defined over signatures of variables by adapting the general institution-independent quantifiers of [Tar86] to the present framework of generalized substitution systems.

**Definition 3.2.8** (Quantified sentence). In any generalized substitution system $\mathcal{S}: \text{Sig} \to \text{SubstSys}$, a *universally quantified* $\Sigma$-sentence is a structure $\forall X \cdot \rho$, where $X$ is a signature of $\Sigma$-variables and $\rho$ is an $X$-sentence. The denotation of $\forall X \cdot \rho$ is given by the class of $\Sigma$-models whose $X$-expansions satisfy $\rho$. To be more precise, a $\Sigma$-model $M$ is a model of $\forall X \cdot \rho$, denoted $M \models^{qs} \forall X \cdot \rho$, if, for every $X$-model $N$ such that $N |_{\Sigma} = M$, $N \models_{\Sigma, X} \rho$.

*Existentially quantified* $\Sigma$-sentences $\exists X \cdot \rho$ are introduced in a similar manner. Their semantics is, as expected, existential rather than universal: the denotation of a sentence $\exists X \cdot \rho$ is given by the class of $\Sigma$-models that admit $X$-expansions satisfying $\rho$.

Let $\text{QSen}(\Sigma)$, or $\text{QSen}^{qs}(\Sigma)$ when we want to make explicit the underlying generalized substitution system, be the set of quantified sentences (universal or existential) over a signature $\Sigma$ of a generalized substitution system $\mathcal{S}: \text{Sig} \to \text{SubstSys}$. It is straightforward to see that the map $\text{QSen}$ can be extended to a functor $\text{Sig} \to \text{Set}$ by defining $\text{QSen}(\phi)(Q X \cdot \rho)$ as $Q \Psi_{\phi}(X) \cdot \alpha_{\phi,X}(\rho)$ for every morphism of signatures $\phi: \Sigma \to \Sigma'$ and every quantified $\Sigma$-sentence $Q X \cdot \rho$, where $Q \in \{\forall, \exists\}$.

**Fact 3.2.9.** For any generalized substitution system $\mathcal{S}: \text{Sig} \to \text{SubstSys}$, $\text{QSen}$ is a *quantified-sentence functor* $\text{Sig} \to \text{Set}$.

In order to reason about programs defined over different signatures, it is necessary to ensure that the translation of quantified sentences is consistent with the reduction of models – in the sense that the satisfaction relation is preserved. As in many institutions that capture logical systems with quantifiers, this condition relies on the essential property of model amalgamation, that is on the possibility of combining models of different but related signatures, provided that they have a common reduct to a given shared signature. The form of model amalgamation that we use here was first introduced in [BPP85]; other early papers include [ST88a; DGS93]. Its importance was also emphasized in works on heterogeneous specifications such as [Taroo; Boroz], which are closely related to our setting.
**Definition 3.2.10 (Model amalgamation).** A generalized substitution system $\mathcal{G}: \text{Sig} \to \text{SubstSys}$ has *(weak) model amalgamation* when, for every signature morphism $\varphi: \Sigma \to \Sigma'$ and every signature of $\Sigma$-variables $X$, the diagram depicted below is a (weak) pullback.

$$
\begin{array}{c}
\text{Mod}(\Sigma) \quad \downarrow \text{\scriptsize{\varphi}} \\
\text{Mod}(\Sigma') \\
\text{Mod}_{\Sigma}(X) \quad \downarrow \text{\scriptsize{\varphi}_X} \\
\text{Mod}_{\Sigma'}(\Psi_{\varphi}(X))
\end{array}
$$

This means that for every $\Sigma'$-model $M'$ and every $X$-model $N$ such that $M' \upharpoonright \varphi = N \upharpoonright \Sigma$ there exists a $\Psi_{\varphi}(X)$-model $N'$, called the *amalgamation* of $M'$ and $N$, that satisfies $N' \upharpoonright \Sigma = M'$ and $\beta_{\varphi,X}(N') = N$. Whenever this holds, the following commutative square, which subsumes the diagram above, is said to be a *(weak) model-amalgamation square*:

$$
\begin{array}{c}
G_{\Sigma} \\
\text{\scriptsize{\varphi}} \\
G_{\Sigma'} \\
\text{\scriptsize{\Psi}_{\varphi}(X)} \\
\text{\scriptsize{\varphi}_X} \\
G_{\Sigma}(X) \quad \downarrow \text{\scriptsize{\Psi}_{\varphi}(X)} \\
G_{\Sigma'}(X)
\end{array}
$$

In generalized substitution systems such as $\varphi$-$\text{FOL}_1$ – as well as, for example, $\varphi$-$\text{FOL}_{\text{em}}$, discussed in Chapter 4 – for every signature morphism $\varphi: \langle F, P \rangle \to \langle F', P' \rangle$ and every signature of $\langle F, P \rangle$-variables $X$, the commutative square of interest for model amalgamation can be obtained by taking the image through $\varphi$-$\text{FOL}_1$ of the following diagram of signature morphisms:

$$
\begin{array}{c}
\langle F, P \rangle \quad \downarrow \text{\scriptsize{\varphi}} \\
\langle F \cup X, P \rangle \quad \downarrow \text{\scriptsize{\varphi}_X} \\
\langle F', P' \rangle \\
\langle F' \cup X^{\varphi}, P' \rangle
\end{array}
$$

It is well known that such diagrams are pushouts and, moreover, that every pushout of first-order signature morphisms gives rise to a model-amalgamation square (details can be found, for example, in [Dia08; ST11]). These considerations lead us to the following result.

**Proposition 3.2.11.** The generalized substitution system $\varphi$-$\text{FOL}_1$ has model amalgamation.

Model amalgamation allows us to prove that the translations of quantified sentences and the reductions of models preserve the satisfaction relation.
**Proposition 3.2.12.** Let $\mathcal{S}: \text{Sig} \to \text{SubstSys}$ be a generalized substitution system that has weak model amalgamation. Then for every signature morphism $\varphi: \Sigma \to \Sigma'$, every quantified $\Sigma$-sentence $QX \cdot \rho$, and every $\Sigma'$-model $M'$,

$$M' \vDash_{\Sigma'}^\mathcal{S} \text{QSen}(\varphi)(QX \cdot \rho) \quad \text{if and only if} \quad \text{Mod}(\varphi)(M') \vDash_{\Sigma}^\mathcal{S} QX \cdot \rho.$$

**Proof.** Since the two kinds of quantified sentences can be treated similarly, we focus here only on the case of universal sentences. Let us thus consider a signature morphism $\varphi: \Sigma \to \Sigma'$, a $\Sigma$-sentence $\forall X \cdot \rho$, and a $\Sigma'$-model $M'$.

The proof of the ‘if’ part is simpler and it does not require the model-amalgamation property. Assume that $\text{Mod}(\varphi)(M') \vDash_{\Sigma}^\mathcal{S} \forall X \cdot \rho$, and let $N'$ be an arbitrary $\Psi_\varphi(X)$-expansion of $M'$. Since $\kappa_\varphi \downarrow \mathcal{S}_\Sigma(\Psi_\varphi(X)) = \mathcal{S} \mathcal{S}_\Sigma(X)$ (because $\langle \Psi_\varphi, \kappa_\varphi, \tau_\varphi \rangle$ is a morphism of substitution systems), it follows that $\beta_{\varphi,X}(N')$ is an $X$-expansion of $\text{Mod}(\varphi)(M')$. As a result, $\beta_{\varphi,X}(N') \vDash_{\Sigma,X} \rho$, which implies, by the satisfaction condition for $\tau_{\varphi,X}$, that $N' \vDash_{\Sigma,\Psi_\varphi(X)} \alpha_{\varphi,X}(\rho)$. Hence, given that, by definition, $\text{QSen}(\varphi)(\forall X \cdot \rho)$ is the universally quantified sentence $\forall \Psi_\varphi(X) \cdot \alpha_{\varphi,X}(\rho)$, we conclude that $M' \vDash_{\Sigma'}^\mathcal{S} \text{QSen}(\varphi)(\forall X \cdot \rho)$.

For the ‘only if’ part, assume that $M'$ is a model of $\text{QSen}(\varphi)(\forall X \cdot \rho)$, and let $N$ be an $X$-expansion of $\text{Mod}(\varphi)(M')$, which means that $\text{Mod}(\varphi)(M') = \beta_{\Sigma,X}(N)$. We need to show that $N$ satisfies $\rho$. Since $\mathcal{S}$ has weak model amalgamation, we deduce that there exists a $\Psi_\varphi(X)$-model $N'$ such that $\beta_{\Sigma,\Psi_\varphi(X)}(N') = M'$ and $\beta_{\varphi,X}(N') = N$. This means that $N'$ is a $\Psi_\varphi(X)$-expansion of $M'$, which further implies that $N' \vDash_{\Sigma,\Psi_\varphi(X)} \alpha_{\varphi,X}(\rho)$ because, by hypothesis, $M' \vDash_{\Sigma'}^\mathcal{S} \forall \Psi_\varphi(X) \cdot \alpha_{\varphi,X}(\rho)$. Therefore, by the satisfaction condition for $\tau_{\varphi,X}$, we have $\beta_{\varphi,X}(N') \vDash_{\Sigma,X} \rho$. \qed

**Corollary 3.2.13.** For any generalized substitution system $\mathcal{S}: \text{Sig} \to \text{SubstSys}$ that has weak model amalgamation, the structure $\mathcal{S}^\mathcal{S}_{\mathcal{S}} = (\text{Sig}, \text{QSen}, \text{Mod}, \vDash^\mathcal{S})$ describes an institution – the institution of quantified sentences over $\mathcal{S}$. \qed

### 3.3 Abstract Logic Programming

As we have seen, generalized substitution systems provide us with a framework that is rich and flexible enough for capturing some of the most essential aspects of logic programming. However, since they make no assumptions on the structure of sentences defined over signatures of variables, we cannot distinguish between clauses and queries, nor can we describe unifiable sentences, which would further enable the search for solutions to queries by means of a suitable concept of resolution. To overcome these limitations, we
extend the notion of generalized substitution system with appropriate fun-
c tors that define local clauses and queries, and with binary inference rules
that allow the integration of the declarative and the operational semantics
of logic programming. The following property gives a concise presentation
of the local sentences defined by a generalized substitution system.

**Fact 3.3.1.** Any generalized substitution system $\$S : \text{Sig} \to \text{SubstSys}$ deter-
m ines a *local-sentence functor* $\text{LSen} : \text{Sig} \to (\_ \to \text{Set})^\$S$, denoted $\text{LSen}^\$S$ when
we want to make explicit the generalized substitution system, that maps

- every signature $\Sigma$ to the pair $(\text{Subst}_\Sigma, \Sigma \subseteq \|\l_{G_{\Sigma}}\| \text{Sen})$, usually identified
  with the second component, the functor $\$S|_{\Sigma} \subseteq \|\l_{G_{\Sigma}}\| \text{Sen} : \text{Subst}_\Sigma \to \text{Set}$, and

- every signature morphism $\phi : \Sigma \to \Sigma'$ to $(\Psi_\phi, \tau_\phi : (\|\l_{G_{\Sigma}}\| \text{Sen}))$.

$$
\begin{align*}
\text{Subst}_\Sigma & \xrightarrow{\$S_\Sigma} G_{\Sigma} / \text{Room} \\
\Psi_\phi & \Downarrow \tau_\phi \\
\text{Subst}_{\Sigma'} & \xrightarrow{\$S_{\Sigma'}} G_{\Sigma'} / \text{Room}
\end{align*}
\xrightarrow{\|\l_{G_{\Sigma}}\| \text{Sen} \to \text{Set}}
\text{LSen}_\Sigma
$$

This means that, for every signature $\Sigma$, the functor $\text{LSen}(\Sigma)$ describes the sets
$\text{LSen}(\Sigma)(X) = \text{Sen}_{\Sigma}(X)$ of local $\Sigma$-sentences, where $X$ is a signature of $\Sigma$-
variables, together with translations of local sentences $\text{LSen}(\Sigma)(\psi) = \text{Sen}_{\Sigma}(\psi)$,
where $\psi$ is a $\Sigma$-substitution. In addition, for every signature morphism $\phi : \Sigma \to \Sigma'$, $\text{LSen}(\phi)$ describes the translation of signatures of $\Sigma$-variables
$\Psi_\phi : \text{Subst}_\Sigma \to \text{Subst}_{\Sigma'}$ and the family of natural maps $\alpha_{\phi,X} : \text{Sen}_{\Sigma}(X) \to
\text{Sen}_{\Sigma'}(\Psi_\phi(X))$, indexed by signatures of $\Sigma$-variables $X$.

We can now define the main algebraic concept that underlies our approach
to logic-independent logic programming.

**Definition 3.3.2 (Logic-programming framework).** A *logic-programming
framework* is a tuple $\mathcal{F} = (\$S, C, Q, \#)$, where

- $\$S is a generalized substitution system that has weak model amalgamation,
- $C$ and $Q$ are generalized subfunctors of $\text{LSen}$, defining the subsets $C_{\Sigma}(X) \subseteq
\text{Sen}_{\Sigma}(X)$ and $Q_{\Sigma}(X) \subseteq \text{Sen}_{\Sigma}(X)$ of X-clauses and X-queries, respectively, for every
signature $\Sigma$ and every signature of $\Sigma$-variables $X$, and
- $\#$ is a generalized subfunctor of $(Q \times C) \times Q$ defining, for every signature $\Sigma$
and signature of $\Sigma$-variables $X$, the subset $\#_{\Sigma,X} \subseteq (Q_{\Sigma}(X) \times C_{\Sigma}(X)) \times Q_{\Sigma}(X)$
of X-goal-directed rules $(\rho_1, \gamma, \rho_2)$, usually denoted by $\rho_1, \gamma \#_{\Sigma,X} \rho_2$,
such that the following soundness property holds for every signature $\Sigma$, sig-
nature of $\Sigma$-variables $X$, X-queries $\rho_1$ and $\rho_2$, and every X-clause $\gamma$:

$$
\rho_1, \gamma \#_{\Sigma,X} \rho_2 \quad \text{implies} \quad \{\rho_2, \gamma\} \#_{\Sigma,X} \rho_1.
$$
Example 3.3.3. Conventional first-order logic programming is defined over
the generalized substitution system $\mathsf{FOL}_1$, as follows: for every signature
$(F, P)$ and every signature of $(F, P)$-variables $X$,

- the set $C_{(F, P)}(X)$ of $X$-clauses consists of all implications of the form $\land H \Rightarrow C$, where $H$ is a finite set of relational atoms and $C$ is an atom,
- the set $Q_{(F, P)}(X)$ of $X$-queries consists of all finite conjunctions of atoms $\land Q$,
- the rules are given by $\land (\{C\} \cup Q)$, $(\land H \Rightarrow C) \models_{(F, P), X} \land (Q \cup H)$.

One can easily see that the (local) first-order clauses, queries, and goal-
directed rules are preserved along both signature morphisms and substitu-
tions; for example, the translation of a clause along a signature morphism,
when regarded as a sentence over the domain signature of that morphism,
is a clause defined over the codomain signature of the morphism. Moreover,
the goal-directed rules correspond, in essence, to applications of modus pon-
ens, and thus they are sound. As a result, the constructions above define a
logic-programming framework, which we denote by $\mathcal{FOL}_1$.

The definitions of clauses and queries are rather straightforward.

Definition 3.3.4 (Clause and query). Let $\Sigma$ be a signature of the underly-
ing generalized substitution system $\mathcal{S}$ of a logic-programming framework
$(\mathcal{S}, C, Q, \models)$. A $\Sigma$-clause is a universally quantified sentence $\forall X \cdot \gamma$ over
$\Sigma$ such that $\gamma \in C_{\Sigma}(X)$. Similarly, a $\Sigma$-query is an existentially quantified sentence $\exists X \cdot \rho$ over $\Sigma$ such that $\rho \in Q_{\Sigma}(X)$.

We obtain in this way two subfunctors $\forall \mathcal{C}$ (defining the clauses) and $\exists \mathcal{Q}$ (defining the queries) of the sentence functor $\mathcal{QSen}$ of the institution of quantified sentences over $\mathcal{S}$ (see Corollary 3.2.13).

Following recent developments in structuring specifications [see Dia12a; Tut13], we propose an axiomatic approach to logic-programming languages
in which programs are treated as abstract entities, each of them defining a
signature (in a given logic-programming framework), a class of models – that
provides the denotational semantics of the program – and an appropriate
set of clauses – that supports the operational semantics of the program.
In addition, programs are related by morphisms that induce appropriate
reductions of models and translations of clauses, defined in terms of their
projections to the underlying logic-programming framework.

Definition 3.3.5 (Logic-programming language). A logic-programming lan-
guage $\mathcal{L} = (\mathcal{LIP}, \text{Sign}, \text{PMod}, \text{Ax})$ over a framework $(\mathcal{S}, C, Q, \models)$ consists of
• a category \( \mathbf{LP} \) of logic programs and morphisms of logic programs,
• a signature functor \( \text{Sign}: \mathbf{LP} \to \text{Sig} \), and
• subfunctors \( \text{PMod} \subseteq \text{Sign}^{\text{op}} \), \( \text{Mod} \subseteq \text{Sign} \) defining, for every program \( P \), the category \( \text{PMod}(P) \) of \( P \)-models and the set \( \text{Ax}(P) \) of \( P \)-clauses,

\[
\begin{array}{c}
\text{LP} \\
\downarrow \text{PMod}^{\text{op}} \\
\downarrow \text{Sign} \\
\downarrow \text{Ax} \\
\downarrow \mathbf{Cat}^{\text{op}} \\
\downarrow \text{Mod}^{\text{op}} \\
\downarrow \text{Set} \\
\end{array}
\]

such that, for every logic program \( P \) and model \( M \) of \( P \), \( M \models_{\text{lp}} \text{Ax}(P) \).

By way of notation, when there is no risk of confusion, we will often denote logic programs \( P \) by \( \langle \Sigma, \Gamma \rangle \), where \( \Sigma = \text{Sign}(P) \) and \( \Gamma = \text{Ax}(P) \), emphasizing in this way their corresponding signatures and sets of clauses; moreover, we may denote simply by \( \nu \) the signature morphism \( \text{Sign}(\nu) \) determined by a morphism of programs \( \nu: P \to P' \). We may also indicate that a \( \Sigma \)-model \( M \) is a model of \( P \) by writing \( M \models_{\text{lp}} P \), and that a quantified \( \Sigma \)-sentence \( QX \cdot \rho \) is semantically entailed by \( P \), meaning that \( M \models_{\text{qs}} \Sigma QX \cdot \rho \) for all \( P \)-models \( M \), by writing \( P \models_{\text{lp}} QX \cdot \rho \).

**Example 3.3.6.** Most of the mechanisms used in defining (structured) specifications can also be used to define logic programs. For instance, one of the simplest and most common descriptions of logic programs is as theory presentations over a logic-programming framework \( \mathcal{F} = \langle \mathcal{S}, C, Q, \vdash \rangle \) such as \( \mathcal{FOL}^1 \) [see e.g. GB92; DGS93]. In this case, the programs defined by the resulting logic-programming language – denoted \( \mathcal{F}^{\text{pres}} \) – are pairs \( \langle \Sigma, \Gamma \rangle \) of signatures \( \Sigma \) of \( \mathcal{S} \) and sets of \( \Sigma \)-clauses \( \Gamma \), while the morphisms \( \varphi: \langle \Sigma, \Gamma \rangle \to \langle \Sigma', \Gamma' \rangle \) are merely signature morphisms \( \varphi: \Sigma \to \Sigma' \) such that \( \Gamma' \models_{\Sigma'} \varphi(\Gamma) \). The functors \( \text{Sign}, \text{Ax}, \text{PMod} \) have their usual interpretations: for every presentation \( \langle \Sigma, \Gamma \rangle \), (a) \( \text{Sign}(\Sigma, \Gamma) \) is the signature \( \Sigma \), (b) \( \text{Ax}(\Sigma, \Gamma) \) is the set of \( \Sigma \)-clauses \( \Gamma \), and (c) \( \text{PMod}(\Sigma, \Gamma) \) is the full subcategory of \( \text{Mod}(\Sigma) \) given by the models of \( \Sigma \) that satisfy \( \Gamma \).

Under this formalism, based on the first-order signature \( \langle \text{FAT}, \text{PAT} \rangle \) considered in Section 3.1 and on the clauses presented in Section 3.2, the logic program that captures the addition of natural numbers can be defined over the logic-programming language \( (\mathcal{FOL}^1)^{\text{pres}} \) as follows:

**signature**

\[
\begin{align*}
\text{ops} & \ 0: 0, \ _{\_}: 1 \\
\text{pred} & \ \text{add}: 3
\end{align*}
\]
axioms
\[
\begin{align*}
\text{add}(0, M, M) & \leftarrow_M - \\
\text{add}(sM, N, sP) & \leftarrow_{M, N, P} - \\
\end{align*}
\]

For the remaining part of this section, we will assume that \( \mathcal{L} \) is an arbitrary but fixed logic-programming language \( \langle \mathcal{LP}, \text{Sign}, \text{PMod}, \text{Ax} \rangle \) over a logic-programming framework \( \mathcal{F} = \langle \mathcal{SS}, \mathcal{C}, \mathcal{Q}, \# \rangle \).

3.3.1 Herbrand’s Theorem

From a model-theoretic perspective, a logic program \( \langle \Sigma, \Gamma \rangle \) gives a positive answer to a \( \Sigma \)-query \( \exists X \cdot \rho \) when it semantically entails the query, which means, of course, that every model of \( \langle \Sigma, \Gamma \rangle \) admits an \( X \)-expansion that satisfies \( \rho \). In practice, this kind of answer is not always adequate for the particular task at hand, as we may be interested in finding the actual ‘values’ for \( X \) – independent of any choice of model of \( \langle \Sigma, \Gamma \rangle \) – that meet all the requirements described by \( \rho \). The notion of solution presented below relies technically on the concept of conservative signature of variables.

**Definition 3.3.7** (Conservative signature of variables). For any signature \( \Sigma \), a signature of \( \Sigma \)-variables \( Y \) is said to be conservative whenever the model-reduct functor \( \beta_{\Sigma,Y} : \text{Mod}_{\Sigma}(Y) \rightarrow \text{Mod}(\Sigma) \) is surjective on objects.

Note that, in the case of the single-sorted fragment of relational first-order logic, a (non-empty) signature of \( \langle F, P \rangle \)-variables is conservative if and only if the set \( F_0 \) of constant-operation symbols is not empty.

**Definition 3.3.8** (Solution). For any logic program \( \langle \Sigma, \Gamma \rangle \), a \( \Sigma \)-substitution \( \psi : X \rightarrow Y \) is a \( \langle \Sigma, \Gamma \rangle \)-solution, or correct \( \langle \Sigma, \Gamma \rangle \)-answer, to a \( \Sigma \)-query \( \exists X \cdot \rho \) if the signature of variables \( Y \) is conservative and \( \langle \Sigma, \Gamma \rangle \vDash_{\Sigma} \forall Y \cdot \psi(\rho) \).

Therefore, we have to consider two notions of answer to a query, both of which are relative to a given logic program: the first one corresponds to the denotational semantics of the logic-programming language, while the second provides the necessary foundations for its operational semantics.

Herbrand’s theorem ensures that the two notions are equivalent. First, it reduces the semantic entailment of the considered query to satisfaction in the initial model of the logic program; then, it shows that any expansion of the initial model that satisfies the underlying local sentence of the query gives rise to a solution, and vice versa. These properties are well known in the literature for various logical systems [see e.g. Llo87; GM87; GMK02], and
they were first investigated in an institution-independent setting in [Dia04]. The result we develop here upgrades the ones from [Dia04] by considering a different set of hypotheses, based on the existence of certain reachable models instead of representable signature morphisms and substitutions; moreover, it can be utilized even when the signatures of variables cannot be described as extensions of their base signatures. These new assumptions are significantly more permissive as they allow us to apply the theory advanced herein to logical systems that, similarly to those discussed in [ŢF13] (and further developed in Section 5.2.1), do not fit into the framework proposed in [Dia04] – which, in fact, can be shown to be a concrete realization of the conceptual structure that we put forward here (see Theorem 4.3.17).

The following concept of reachable model extends (non-trivially) the homonymous one from [GP10] to generalized substitution systems by eliminating the need for an initial signature of variables with the same sentences, models, and satisfaction relation as its corresponding base signature.

**Definition 3.3.9** (Reachable model). Let \( \Sigma \) be a signature and \( X \) a signature of \( \Sigma \)-variables in a generalized substitution system. A \( \Sigma \)-model \( M \) is said to be \( X \)-reachable when for every \( X \)-expansion \( N \) of \( M \) there exists a \( \Sigma \)-substitution \( \psi : X \rightarrow Y \) such that

- \( Y \) is conservative and
- the canonical map \( \rho_{\Sigma} : N / \text{Mod}_\Sigma(\psi) \rightarrow M / \beta_{\Sigma,Y} \) determined by the reduct functor \( \beta_{\Sigma,X} \) is surjective on objects.

Hence, given a model \( N \) and a substitution \( \psi \) as above, the \( \Sigma \)-model \( M \) is \( X \)-reachable if every homomorphism \( h : M \rightarrow N_1 \upharpoonright \Sigma \) from \( M \) to the \( \Sigma \)-reduct of an \( Y \)-model \( N_1 \) admits an \( X \)-expansion of the form \( f : N \rightarrow N_1 \upharpoonright \psi \).

In many concrete examples of institutions [see e.g. GP10], a model \( M \) is reachable (with respect to some signature of variables) if and only if all its elements are interpretations of terms, that is if the unique homomorphism \( 0_\Sigma \rightarrow M \) from the initial model of the signature of \( M \) to \( M \) is epi. In particular, for first-order logic, the initial model \( 0_{(F,P),\Gamma} \) of a set \( \Gamma \) of \( (F,P) \)-clauses is \( X \)-reachable for every signature of \( (F,P) \)-variables \( X \): every expansion \( N_{(F,P),\Gamma} \) of \( 0_{(F,P),\Gamma} \) yields a substitution \( \psi : X \rightarrow \emptyset \) to the empty signature of variables (which is conservative, and has the same models as \( (F,P) \)) such that \( 0_{(F,P),\Gamma} \upharpoonright \psi = N_{(F,P),\Gamma} \upharpoonright \psi \); hence, every homomorphism \( h : 0_{(F,P),\Gamma} \rightarrow N_1 \upharpoonright (F,P) \) in \( \text{Mod}(F,P) \) admits an \( X \)-expansion \( N_{(F,P),\Gamma} \rightarrow N_1 \upharpoonright \psi \) given by \( h \upharpoonright \psi \).

**Proposition 3.3.10.** In \((\mathcal{FOC}_1^\Sigma)^\text{pres}\), every program \( (F,P),\Gamma \) admits an initial model \( 0_{(F,P),\Gamma} \) that is reachable with respect to all signatures of \( (F,P) \)-variables. \( \square \)
In addition to the existence of particular reachable models, we also require (as in [Diao04]) that model homomorphisms preserve the satisfaction of the local sentence upon which the query under consideration is based.

**Definition 3.3.11** (Preservation of satisfaction). Given a signature $\Sigma$ and a signature of $\Sigma$-variables $X$ in a generalized substitution system $\text{GSS} : \text{Sig} \rightarrow \text{SubstSys}$, an $X$-homomorphism $h : N_1 \rightarrow N_2$ is said to preserve the satisfaction of an $X$-sentence $\rho$ if $N_1 \models_{\Sigma,X} \rho$ implies $N_2 \models_{\Sigma,X} \rho$.

Note that, in the case of $\text{qFOL}_x^1$, all homomorphisms preserve, by definition, the satisfaction of all relational atoms. This property can be easily extended to arbitrary conjunctions of atoms, and thus to local queries of $\text{FOL}_x^1$.

**Fact 3.3.12.** In the logic-programming framework $\text{FOL}_x^1$, all homomorphisms preserve the satisfaction of all local queries.

**Theorem 3.3.13** (Herbrand’s theorem). For every logic program $\langle \Sigma, \Gamma \rangle$ and every $\Sigma$-query $\exists X \cdot \rho$ such that (a) $\langle \Sigma, \Gamma \rangle$ has an $X$-reachable initial model $0_{\langle \Sigma, \Gamma \rangle}$, and (b) the satisfaction of $\rho$ is preserved by $X$-homomorphisms, the following statements are equivalent:

1. $\langle \Sigma, \Gamma \rangle \models_{\Sigma} \exists X \cdot \rho$.
2. $0_{\langle \Sigma, \Gamma \rangle} \models_{\Sigma} \exists X \cdot \rho$.
3. $\exists X \cdot \rho$ admits a $\langle \Sigma, \Gamma \rangle$-solution.

**Proof.**

1 $\Rightarrow$ 2. Obvious, since $0_{\langle \Sigma, \Gamma \rangle} \models_{\Sigma} \exists X \cdot \rho$.

2 $\Rightarrow$ 3. By hypothesis, there exists an $X$-expansion $N_{\langle \Sigma, \Gamma \rangle}$ of $0_{\langle \Sigma, \Gamma \rangle}$ such that $N_{\langle \Sigma, \Gamma \rangle} \models_{\Sigma,X} \rho$. Since $0_{\langle \Sigma, \Gamma \rangle}$ is assumed to be $X$-reachable, we know that there exists a substitution $\psi : X \rightarrow Y$ (corresponding to the model $N_{\langle \Sigma, \Gamma \rangle}$) satisfying the two properties listed in Definition 3.3.9. Therefore, we only need to show that $\langle \Sigma, \Gamma \rangle \models_{\Sigma} \forall Y \cdot \psi(\rho)$.

Let us thus consider a model $M$ of $\langle \Sigma, \Gamma \rangle$ and a $Y$-expansion $N$ of $M$. Based on the initiality property of $0_{\langle \Sigma, \Gamma \rangle}$, we obtain a (unique) $\Sigma$-homomorphism $h : 0_{\langle \Sigma, \Gamma \rangle} \rightarrow M = N \upharpoonright_{\Sigma}$, which can be lifted, by taking into account the surjectivity of the map $\upharpoonright_{\Sigma} : N_{\langle \Sigma, \Gamma \rangle} / \text{Mod}_\Sigma(\psi) \rightarrow 0_{\langle \Sigma, \Gamma \rangle} / \beta_{\Sigma,Y}$, to an $X$-homomorphism $f : N_{\langle \Sigma, \Gamma \rangle} \rightarrow N \upharpoonright_\psi$. Since $f$ preserves the satisfaction of $\rho$ (by hypothesis) and $N_{\langle \Sigma, \Gamma \rangle} \models_{\Sigma,X} \rho$, it follows that $N \upharpoonright_\psi \models_{\Sigma,X} \rho$, which implies, by the satisfaction condition for $\psi$, that $N \models_{\Sigma,Y} \psi(\rho)$. Hence, $M \models_{\Sigma} \forall Y \cdot \psi(\rho)$.

3 $\Rightarrow$ 1. Assume that $\psi : X \rightarrow Y$ is a $\langle \Sigma, \Gamma \rangle$-solution to $\exists X \cdot \rho$, and that $M$ is a model of $\langle \Sigma, \Gamma \rangle$. This means that $\langle \Sigma, \Gamma \rangle \models_{\Sigma} \forall Y \cdot \psi(\rho)$, and thus
$M \models_{\Sigma}^q Y \cdot \psi(\rho)$. In addition, $Y$ is conservative, from which we deduce that there exists a $Y$-expansion $N$ of $M$ such that $N \models_{\Sigma,Y} \psi(\rho)$. It follows by the satisfaction condition for $\psi$ that $N \models_{\psi}$ is an $X$-expansion of $M$ such that $N \models_{\psi} \models_{\Sigma,X} \rho$. Consequently, $M \models_{\Sigma}^q \exists X \cdot \rho$. \hfill \Box

**Remark 3.3.14.** The additional hypotheses referring to the existence of a reachable initial model of $\langle \Sigma, \Gamma \rangle$ and to the preservation of the satisfaction of $\rho$ by homomorphisms are used only in the proof of the ‘completeness’ part of Theorem 3.3.13, that is for the implication $1 \Rightarrow 3$; the ‘soundness’ part, corresponding to the implication $3 \Rightarrow 1$, holds for every logic program $\langle \Sigma, \Gamma \rangle$ (defined over an arbitrary language) and every $\Sigma$-query $\exists X \cdot \rho$.

### 3.3.2 Operational Semantics

One of the most important (and distinctive) features of the concept of logic-programming language is that it allows us to make effective use of the resolution inference rule and, in a very natural way, to give an operational semantics to logic programs. Consider, for instance, the logic program $\langle \{ \text{nat}, \text{plus} \}, \Gamma \rangle$ described in Example 3.3.6 and the query $\exists X_1 \cdot \text{add}(s \ 0, s \ 0, X_1)$, sometimes written as

$$\leftarrow_{X_1} \text{add}(s \ 0, s \ 0, X_1)$$

using a notation similar to that of clauses. We can compute a solution to the query $\exists X_1 \cdot \text{add}(s \ 0, s \ 0, X_1)$ using the clauses of $\Gamma$ and the goal-directed rules of $\text{TOCL}_{}$ as follows: we first derive the query $\exists X_2 \cdot \text{add}(\emptyset, s \ 0, X_2)$, based on the second clause of $\Gamma$, the substitutions $\theta_1 : \{X_1\} \rightarrow \{X_2\}$ and $\psi_1 : \{M, N, P\} \rightarrow \{X_2\}$ given by $X_1 \mapsto s \ X_2$, $M \mapsto \emptyset$, $N \mapsto s \emptyset$ and $P \mapsto X_2$, and the following goal-directed rule over $\{X_2\}$;

by iterating these constructions, we can further derive the trivial query $\exists \emptyset \cdot \text{true}$ using the first clause of $\Gamma$, the substitutions $\theta_2 : \{X_2\} \rightarrow \emptyset$ and $\psi_2 : \{M\} \rightarrow \emptyset$ given by $X_2 \mapsto s \emptyset$ and $M \mapsto s \emptyset$, and the goal-directed rule over $\emptyset$ detailed below;

4 Moreover, it would suffice to assume that the model $0_{\Sigma,\Gamma}$ is weakly initial.
finally, we compose the substitutions \( \theta_1 \) and \( \theta_2 \) (which are usually computed through term unification) to obtain a solution to \( \exists X_1 \cdot \text{add}(s \emptyset, s \emptyset, X_1) \).

The procedure outlined above does not depend on any particular details of \( \mathcal{FO}L^1_{\pi} \text{pres} \); in fact, it admits a straightforward formalization within the abstract framework of logic-programming languages.

**Definition 3.3.15** (Resolution). Let \( \exists X_1 \cdot \rho_1 \) be a query and \( \forall Y_1 \cdot \gamma_1 \) a clause over a signature \( \Sigma \). A \( \Sigma \)-query \( \exists X_2 \cdot \rho_2 \) is said to be derived by resolution from \( \exists X_1 \cdot \rho_1 \) and \( \forall Y_1 \cdot \gamma_1 \) using the computed substitution \( \theta_1 : X_1 \rightarrow X_2 \) if there exists a substitution \( \psi_1 : Y_1 \rightarrow X_2 \) such that \( \theta_1(\rho_1), \psi_1(\gamma_1) \vdash \Sigma, X_2 \rho_2 \).

\[
\begin{array}{c}
\exists X_1 \cdot \rho_1 \\
\forall Y_1 \cdot \gamma_1
\end{array}
\xrightarrow{\theta_1}
\exists X_2 \cdot \rho_2
\]

**Unification.** Note that resolution describes not only the derivation of new and (presumably) simpler queries from appropriate pairs of queries and clauses, but also how partial answers to the original queries can be computed by means of *sentence unification*. In this sense, for any signature \( \Sigma \) and signatures of \( \Sigma \)-variables \( X_1 \) and \( Y_1 \), an ordered pair \( \langle \rho_1, \gamma_1 \rangle \) of sentences \( \rho_1 \in Q_{\Sigma}(X_1) \) and \( \gamma_1 \in C_{\Sigma}(Y_1) \) is *unifiable* if there exists a pair \( \langle \theta_1, \psi_1 \rangle \) of substitutions \( \theta_1 : X_1 \rightarrow X_2 \) and \( \psi_1 : Y_1 \rightarrow X_2 \), called the *unifier* of \( \rho_1 \) and \( \gamma_1 \), such that \( \theta_1(\rho_1), \psi_1(\gamma_1) \vdash \Sigma, X_2 \rho_2 \) for some \( X_2 \)-sentence \( \rho_2 \in Q_{\Sigma}(X_2) \).

It is also possible to distinguish between the various levels of generality of the unifiers. Given two unifiers \( \langle \theta_1, \psi_1 \rangle \) and \( \langle \theta'_1, \psi'_1 \rangle \) of \( \rho_1 \) and \( \gamma_1 \) as depicted below, we say that \( \langle \theta'_1, \psi'_1 \rangle \) is an *instance* of \( \langle \theta_1, \psi_1 \rangle \), or that \( \langle \theta_1, \psi_1 \rangle \) is *more general* than \( \langle \theta'_1, \psi'_1 \rangle \), if there exists a substitution \( \theta \) such that \( \theta_1 \upharpoonright \theta = \theta'_1 \) and \( \psi_1 \upharpoonright \theta = \psi'_1 \). Given this, the unifiers of \( \rho_1 \) and \( \gamma_1 \) can be defined as objects of a subcategory of the category of \( \Sigma \)-substitutions.

\[
\begin{array}{c}
X_1 \\
\xrightarrow{\theta_1}
\theta'_1 \\
\downarrow \theta \\
X_2 \\
\xrightarrow{\psi_1}
\psi'_1
\end{array}
\xrightarrow{\theta_1}
Y_1
\]

It should be noted however that, under the present formalization, the most general unifiers, defined as initial objects in their corresponding category (along the lines of [Gog80]), cannot be guaranteed to exist. Even in the case of the logic-programming framework \( \mathcal{FO}L^1_{\pi} \), one cannot find, for example, a most general unifier of the sentences \( \text{add}(s \emptyset, s \emptyset, X_1) \land \text{add}(s s \emptyset, \emptyset, X_1) \) and \( \text{add}(M, N, P) \Rightarrow \text{add}(s M, N, s P) \) — although one exists for \( \text{add}(s \emptyset, s \emptyset, X_1) \).
and \( \text{add}(M, N, P) \Rightarrow \text{add}(sM, N, sP) \), as well as for \( \text{add}(s \circ \theta, \theta, X_1) \) and \( \text{add}(M, N, P) \Rightarrow \text{add}(sM, N, sP) \). This does not restrict the applicability of the theory proposed here, because our abstract notion of resolution actually corresponds to an extended variant of first-order resolution, in which any unifier may give rise to a derivation, not just the most general ones.

The scope of Definition 3.3.15 can be easily broadened to accommodate sets of clauses: given a set \( \Gamma \) of clauses over a signature \( \Sigma \), a \( \Sigma \)-query \( \exists X_2 \cdot \rho_2 \) is said to be derived by resolution from \( \exists X_1 \cdot \rho_1 \) and \( \Gamma \) using the computed substitution \( \theta_1 : X_1 \rightarrow X_2 \), written

\[
\exists X_1 \cdot \rho_1 \rightarrow_{\Gamma, \theta_1} \exists X_2 \cdot \rho_2,
\]

if \( \exists X_2 \cdot \rho_2 \) can be derived by resolution from \( \exists X_1 \cdot \rho_1 \) and \( \forall Y_1 \cdot \gamma_1 \) using the computed substitution \( \theta_1 \), for some \( \Sigma \)-clause \( \forall Y_1 \cdot \gamma_1 \in \Gamma \). This gives us a family \( (-\rightarrow_{\Gamma, \theta})_{\theta \in \text{Subst}} \) of one-step derivation relations generated by \( \Gamma \), whose union is denoted by \( -\rightarrow_{\Gamma} \).

The rest of this section is devoted to the composition of one-step derivations, which will be shown to provide a general procedure for computing answers to queries. To this purpose, let us first investigate the soundness of the one-step derivation relations with respect to the concept of solution.

**Proposition 3.3.16.** Let \( \langle \Sigma, \Gamma \rangle \) be a logic program, and \( \exists X_1 \cdot \rho_1 \) and \( \exists X_2 \cdot \rho_2 \) two \( \Sigma \)-queries. For every inference step \( \exists X_1 \cdot \rho_1 \rightarrow_{\Gamma, \theta_1} \exists X_2 \cdot \rho_2 \) and every solution \( \psi : X_2 \rightarrow Y \) to \( \exists X_2 \cdot \rho_2 \), the substitution \( \theta_1 \circ \psi \) is a solution to \( \exists X_1 \cdot \rho_1 \).

**Proof.** Assume that \( \exists X_2 \cdot \rho_2 \) is derived by resolution from \( \exists X_1 \cdot \rho_1 \) and \( \Gamma \) using the substitution \( \theta_1 : X_1 \rightarrow X_2 \), and that \( \psi : X_2 \rightarrow Y \) is a \( \langle \Sigma, \Gamma \rangle \)-solution to \( \exists X_2 \cdot \rho_2 \). The latter implies that the codomain \( Y \) of \( \theta_1 \circ \psi \) is conservative. Therefore, we only need to prove that \( \langle \Sigma, \Gamma \rangle \vdash^\text{lp} Y \cdot ((\theta_1 \circ \psi) (\rho_1)) \).

Let \( M \) be a model of \( \langle \Sigma, \Gamma \rangle \) and \( N \) a \( Y \)-expansion of \( M \). By the definition of the one-step derivation relation \( -\rightarrow_{\Gamma, \theta_1} \), there exists a clause \( \forall Y_1 \cdot \gamma_1 \in \Gamma \) and a substitution \( \psi_1 : Y_1 \rightarrow X_2 \) such that \( \theta_1 (\rho_1), \psi_1 (\gamma_1) \vdash_{\Sigma, X_2} \rho_2 \). This allows us to deduce, based on the soundness of the goal-directed rules, that \( \{\rho_2, \psi_1 (\gamma_1)\} \vdash_{\Sigma, X_2} \theta_1 (\rho_1) \). Furthermore, since the semantic consequence is preserved by translation along signature morphisms (which, in turn, is an immediate consequence of the invariance of truth under change of notation), we obtain \( \{\psi (\rho_2), (\psi_1 \psi) (\gamma_1)\} \vdash_{\Sigma, Y} (\theta_1 \psi) (\rho_1) \). This means that, to conclude our proof, it suffices to show that \( N \) satisfies both \( \psi (\rho_2) \) and \( (\psi_1 \psi) (\gamma_1) \).

In the case of the first relation, since, by hypothesis, the substitution \( \psi \) is a \( \langle \Sigma, \Gamma \rangle \)-solution to the query \( \exists X_2 \cdot \rho_2 \), we have \( \langle \Sigma, \Gamma \rangle \vdash^\text{lp} Y \cdot \psi (\rho_2) \). It
follows that \( M \models^* \forall \psi \cdot \psi(\rho_2) \), which further implies \( N \models_{\Sigma,Y} \psi(\rho_2) \).

In the case of the second relation, by the general properties of substitution systems, we know that \( N \models_{\psi_1} \psi \) is a \( Y_1 \)-expansion of \( M \). As a result, \( N \models_{\psi_1} \psi \models_{\Sigma,Y_1} \gamma_1 \), because \( M \models_{\Sigma} \forall Y_1 \cdot \gamma_1 \), and thus, by the satisfaction condition for \( \psi_1 \models \psi \), \( N \models_{\Sigma,X_2} (\psi_1 \models \psi)(\gamma_1) \).

\( \square \)

The search for (computed) solutions to a given query proceeds by means of a sequence of one-step derivations, each of which contributes towards the final answer through its corresponding computed substitution.

**Definition 3.3.17** (Derivation). For any set \( \Gamma \) of clauses over \( \Sigma \), and any two \( \Sigma \)-queries \( \exists X_1 \cdot \rho_1 \) and \( \exists X_n \cdot \rho_n \), a \( \Gamma \)-derivation of \( \exists X_n \cdot \rho_n \) from \( \exists X_1 \cdot \rho_1 \) is a chain of one-step derivations

\[
\exists X_1 \cdot \rho_1 \rightarrow_{\Gamma, \theta_1} \exists X_2 \cdot \rho_2 \rightarrow_{\Gamma, \theta_2} \exists X_3 \cdot \rho_3 \cdots \exists X_{n-1} \cdot \rho_{n-1} \rightarrow_{\Gamma, \theta_{n-1}} \exists X_n \cdot \rho_n.
\]

Whenever such a chain exists, the query \( \exists X_n \cdot \rho_n \) is said to be derived from \( \exists X_1 \cdot \rho_1 \) and \( \Gamma \) using the computed substitution \( \theta = \theta_1 \upharpoonright \theta_2 \upharpoonright \cdots \upharpoonright \theta_{n-1} \); in this case, we write \( \exists X_1 \cdot \rho_1 \rightarrow^*_{\Gamma, \theta} \exists X_n \cdot \rho_n \). By definition, if the chain depicted above is empty, \( \exists X_1 \cdot \rho_1 \rightarrow^*_{\Gamma, \theta} \exists X_1 \cdot \rho_1 \). We obtain in this way a family \( (\rightarrow^*_{\Gamma, \theta})_{\theta \in \text{Subst}_{\Sigma}} \) of derivation relations generated by \( \Gamma \).

**Remark 3.3.18.** The union of \( (\rightarrow^*_{\Gamma, \theta})_{\theta \in \text{Subst}_{\Sigma}} \) is the reflexive and transitive closure of the one-step derivation relation \( \rightarrow_{\Gamma} \).

**Proposition 3.3.16** can be generalized without difficulty from one-step to arbitrary derivations by induction on the length of the derivation.

**Corollary 3.3.19.** Let \( (\Sigma, \Gamma) \) be a logic program, and \( \exists X_1 \cdot \rho_1 \) and \( \exists X_n \cdot \rho_n \) two \( \Sigma \)-queries. For every derivation \( \exists X_1 \cdot \rho_1 \rightarrow^*_{\Gamma, \theta} \exists X_n \cdot \rho_n \) and every solution \( \psi : X_n \rightarrow Y \) to \( \exists X_n \cdot \rho_n \), the substitution \( \theta \upharpoonright \psi \) is a solution to \( \exists X_1 \cdot \rho_1 \).

\( \square \)

All we require now in order to define computed answers is a concept of trivial query, which is meant to characterize the successful termination of the search procedure.

**Definition 3.3.20** (Trivial query). Given a signature \( \Sigma \), a \( \Sigma \)-query \( \exists Y \cdot \top \) is said to be trivial if \( Y \) is conservative and every \( Y \)-model satisfies \( \top \).

**Fact 3.3.21.** In the logic-programming framework \( \mathcal{FL}_\Sigma^1 \), a query is trivial if and only if it is of the form \( \exists Y \cdot \text{true} \).

---

\(^5\) Note that, to ensure the conservativity of non-empty signatures of variables, the considered first-order signature has to define at least one constant.
An immediate consequence of the definition above is that every trivial query corresponds to a local tautology (and, even more, the query itself is a tautology). As a result, for every logic program \( \langle \Sigma, \Gamma \rangle \) and every trivial \( \Sigma \)-query \( \exists Y \cdot \top \), we have \( \langle \Sigma, \Gamma \rangle \vdash_{\Sigma} \forall Y \cdot \top \). This amounts to describing the identity \( 1_{\gamma} \) as a \( \langle \Sigma, \Gamma \rangle \)-solution to \( \exists Y \cdot \top \).

**Fact 3.3.22.** Every trivial query \( \exists Y \cdot \top \) over the signature \( \Sigma \) of a logic program \( \langle \Sigma, \Gamma \rangle \) admits a \( \langle \Sigma, \Gamma \rangle \)-solution: the identity substitution \( 1_{\gamma} \).

**Definition 3.3.23 (Computed answer).** Given a program \( \langle \Sigma, \Gamma \rangle \), a \( \Sigma \)-substitution \( \theta: X \rightarrow Y \) is a computed \( \langle \Sigma, \Gamma \rangle \)-answer to a \( \Sigma \)-query \( \exists X \cdot \rho \) if there exists a trivial query \( \exists Y \cdot \top \) such that \( \exists X \cdot \rho \rightarrow^{*}_{\Gamma, \theta} \exists Y \cdot \top \).

Corollary 3.3.19 and Fact 3.3.22 lead to our first main result related to the operational semantics of abstract logic-programming languages.

**Theorem 3.3.24** (Soundness of resolution). Consider a logic program \( \langle \Sigma, \Gamma \rangle \) and a \( \Sigma \)-query \( \exists X \cdot \rho \). Then every computed \( \langle \Sigma, \Gamma \rangle \)-answer to \( \exists X \cdot \rho \) is also a solution to \( \exists X \cdot \rho \).

### 3.3.3 Completeness

As expected, completeness is more difficult to obtain, and requires additional hypotheses. To simplify the proof, we consider two lemmas, each of which introduces a new property to be satisfied by the query at hand or by the considered logic program. The first lemma allows us to derive by resolution any translation (along a substitution) of a given query, which is reminiscent of the well-known lifting lemma of conventional logic programming [see e.g. Av82; Llo87]; the second lemma reduces the search for solutions to a sequence of elementary inferences in a local institution of substitutions – which, in the case of first-order logic-programming, involves no quantifiers.

**Definition 3.3.25 (Identity clause).** Let \( \exists X \cdot \rho \) be a query over a signature \( \Sigma \). A \( \Sigma \)-clause \( \forall X \cdot \gamma \) is an identity of \( \exists X \cdot \rho \) if \( \gamma \) is a tautology and \( \rho, \gamma \vdash_{\Sigma, X} \rho \).

**Fact 3.3.26.** In \( \text{FO} \mathcal{L}^1_{\Sigma} \), every non-trivial query \( \exists X \cdot \gamma \land Q \) admits an identity \( \forall X \cdot \pi(t_1, \ldots, t_n) \Rightarrow \pi(t_1, \ldots, t_n) \), where \( \pi(t_1, \ldots, t_n) \) is an atom in \( Q \).

**Lemma 3.3.27.** Consider a signature \( \Sigma \), a \( \Sigma \)-query \( \exists X \cdot \rho \), and an identity \( \forall X \cdot \gamma \) of \( \exists X \cdot \rho \). For every \( \Sigma \)-substitution \( \psi: X \rightarrow Y \) there exists a one-step derivation of \( \exists Y \cdot \psi(\rho) \) from \( \exists X \cdot \rho \) and \( \forall X \cdot \gamma \) having \( \psi \) as the computed substitution.

\[
\exists X \cdot \rho \rightarrow^{\forall X \cdot \gamma, \psi} \exists Y \cdot \psi(\rho)
\]
proof. Because $\forall X \cdot \gamma$ is the identity of $\exists X \cdot \rho$, we know that $\rho, \gamma \not\vdash_{\Sigma,X} \rho$. This implies $\psi(\rho), \psi(\gamma) \not\vdash_{\Sigma,Y} \psi(\rho)$ because, by the functoriality of $\not\vdash$, the goal-directed rules are preserved along substitutions. It follows that $(\psi, \psi)$ is a unifier of $\rho$ and $\gamma$, which allows us to conclude that $\exists Y \cdot \psi(\rho)$ can be derived by resolution from $\exists X \cdot \rho$ and $\forall X \cdot \gamma$ using the substitution $\psi$. □

The second lemma is based on the following concept of instance of a set of clauses, which, together with the generalization of goal-directed rules to sets of clauses, provides an essential characterization of the derivation relation.

**Definition 3.3.28** (Instance of a set of clauses). Given a set $\Gamma$ of clauses over $\Sigma$ and a signature of $\Sigma$-variables $X$, the $X$-instance of $\Gamma$ is defined as the set $X(\Gamma)$ of all $X$-sentences that can be obtained by translating the local clauses of $\Gamma$ along substitutions into $X$.

$$X(\Gamma) = \{ \psi(\gamma) \in \text{Sen}_\Sigma(X) \mid \forall Y \cdot \gamma \in \Gamma \text{ and } \psi : Y \rightarrow X\}$$

**Definition 3.3.29.** For every signature $\Sigma$ and signature of $\Sigma$-variables $X$, $\not\vdash_{\Sigma,X}$ can be extended to a set $\not\vdash_{\Sigma,X}^*$ of goal-directed rules between $X$-queries and sets of $X$-clauses as follows: given two queries $\rho_1, \rho_n \in Q_\Sigma(X)$ and a (possibly empty) set of clauses $G \subseteq C_\Sigma(X)$,

$$\rho_1, G \not\vdash_{\Sigma,X}^* \rho_n$$

if there exists an alternating sequence $\rho_1 \gamma_1 \rho_2 \gamma_2 \rho_3 \cdots \rho_{n-1} \gamma_{n-1} \rho_n$ of queries $\rho_i \in Q_\Sigma(X)$ and clauses $\gamma_i \in G$ such that $\rho_i, \gamma_i \not\vdash_{\Sigma,X} \rho_{i+1}$ for each index $1 \leq i < n$.

$$\begin{array}{cccc}
\gamma_1 & \gamma_2 & \cdots & \gamma_{n-1} \\
\rho_1 & \rho_2 & \cdots & \rho_{n-1} & \rho_n
\end{array}$$

This gives rise to a generalized subfunctor $\not\vdash^*$ of $(Q \times C_\Sigma)[\mathcal{P}]^2 \times Q$.  

**Proposition 3.3.30.** For all sets $\Gamma$ of clauses over some signature $\Sigma$, queries $\exists X_1 \cdot \rho_1$ and $\exists X_n \cdot \rho_n$ over $\Sigma$, and all (computed) substitutions $\theta : X_1 \rightarrow X_n$,

$$\exists X_1 \cdot \rho_1 \not\vdash_{\Gamma,\theta}^* \exists X_n \cdot \rho_n \quad \text{if and only if} \quad \theta(\rho_1), X_n(\Gamma) \not\vdash_{\Sigma,X_n}^* \rho_n.$$  

proof. We prove the result by induction on the length of the derivation. For the base case, the conclusion can be inferred directly from the definitions of

---

6 We recall from Fact 2.1.8 and Definition 3.3.2 that $C_\Sigma[\mathcal{P}]$ is the functor that maps every signature $\Sigma$ and every signature of $\Sigma$-variables $X$ to the set $\mathcal{P}(C_\Sigma(X))$ of sets of $X$-clauses.
we conclude that because of this, in the following we will focus entirely on the more interesting case that corresponds to the induction step.

For the ‘if’ part, assume there exists an \( X_n \)-query \( \rho_2 \) and an \( X_n \)-clause \( \psi_1(\gamma_1) \in X_n(\Gamma) \), further indicating the existence of a clause \( \forall Y_1 \cdot \gamma_1 \) in \( \Gamma \) and of a substitution \( \psi_1 : Y_1 \rightarrow X_n \) such that \( \theta(\rho_1), \psi_1(\gamma_1) \not\vdash_{\Sigma, X_n} \rho_2 \) and \( \rho_2, X_n(\Gamma) \not\vdash_{\Sigma, X_n} \rho_n \). Based on the definition of resolution and on the induction hypothesis, we deduce that \( \exists X_1 \cdot \rho_1 \rightarrow_{\Gamma, \theta} \exists X_n \cdot \rho_2 \) and \( \exists X_n \cdot \rho_2 \rightarrow_{\Gamma, \theta} \exists X_n \cdot \rho_n \); therefore, by the composition of these derivations, we obtain \( \exists X_1 \cdot \rho_1 \rightarrow_{\Gamma, \theta} \exists X_n \cdot \rho_n \).

For the ‘only if’ part, let \( \theta_1 \neq \theta_2 \) be a factorization of the substitution \( \theta \) such that \( \exists X_1 \cdot \rho_1 \rightarrow_{\Gamma, \theta_1} \exists X_2 \cdot \rho_2 \) and \( \exists X_2 \cdot \rho_2 \rightarrow_{\Gamma, \theta_2} \exists X_n \cdot \rho_n \). Then, by the induction hypothesis, \( \theta_2(\rho_2), X_n(\Gamma) \not\vdash_{\Sigma, X_n} \rho_n \). We also know, by the definition of resolution, that there exists a clause \( \forall Y_1 \cdot \gamma_1 \in \Gamma \) and a substitution \( \psi_1 : Y_1 \rightarrow X_2 \) such that \( \theta_1(\rho_1), \psi_1(\gamma_1) \not\vdash_{\Sigma, X_2} \rho_2 \). Based on the functoriality of \( \vdash_{\Sigma} \), this implies that \( (\theta_1 \neq \theta_2)(\rho_1), (\psi_1 \neq \psi_2)(\gamma_1) \not\vdash_{\Sigma, X_2} \theta_2(\rho_2) \), and thus, since \( (\psi_1 \neq \psi_2)(\gamma_1) \) belongs to \( X_n(\Gamma) \) and \( \theta_2(\rho_2), X_n(\Gamma) \not\vdash_{\Sigma, X_n} \rho_n \), we conclude that \( \theta(\rho_1), X_n(\Gamma) \not\vdash_{\Sigma, X_n} \rho_n \).

Let us recall that, in general, the derivation of queries proceeds by selecting, at each step, a new rule – over a new signature of variables – to be applied to the current goal. Provided that we know the result of the derivation, Proposition 3.3.30 allows us to reduce the derivation of queries to applications of goal-directed rules that are defined over the same signature of variables. In view of this characterization, the soundness of resolution can be interpreted locally as described in the following corollary.

**Corollary 3.3.31.** Let \( \langle \Sigma, \Gamma \rangle \) be a logic program, \( X \) a conservative signature of \( \Sigma \)-variables, and \( \rho \) an \( X \)-query. Then for every trivial \( X \)-query \( \top \),

\[
\rho, X(\Gamma) \not\vdash_{\Sigma, X} \top \quad \text{implies} \quad \langle \Sigma, \Gamma \rangle \vdash_{\Sigma} \forall X \cdot \rho.
\]

**Proof.** Assume \( \top \) to be a trivial query over \( X \) such that \( \rho, X(\Gamma) \not\vdash_{\Sigma, X} \top \). By Proposition 3.3.30, it follows that \( \exists X \cdot \rho \rightarrow_{\Gamma, 1_X} \exists X \cdot \top \). This means that the identity \( 1_X \) is a computed \( \langle \Sigma, \Gamma \rangle \)-answer to \( \exists X \cdot \rho \) (because \( X \) is conservative), and thus, by Theorem 3.3.24, \( 1_X \) is also a solution to \( \exists X \cdot \rho \). As a result, \( \langle \Sigma, \Gamma \rangle \vdash_{\Sigma} \forall X \cdot \rho \).

With respect to the completeness of resolution, we are interested in the converse of the implication discussed in the corollary above. This may hold for certain programs in logic-programming languages of interest, but it cannot be guaranteed in general.
**Definition 3.3.32** (Query-completeness). A logic program \( \langle \Sigma, \Gamma \rangle \) is said to be **query-complete** if for every conservative signature of \( \Sigma \)-variables \( X \) and every \( X \)-query \( \rho \),

\[
\langle \Sigma, \Gamma \rangle \vdash^*_\Sigma \forall X \cdot \rho \quad \text{implies} \quad \rho, X(\Gamma) \vdash^*_\Sigma,X \top
\]

for some trivial \( X \)-query \( \top \). In addition, the logic-programming language \( \mathcal{L} \) is **query-complete** when all logic programs of \( \mathcal{L} \) have this property.

The following result is well known in the literature; it can be found, for instance, in [Llo87]. The result is based on the observation that for every signature of variables \( X \) over a first-order signature \( \langle F, P \rangle \), and for every set \( \Gamma \) of clauses over \( \langle F, P \rangle \), the \( X \)-expansion \( N \) of the free \( \langle F, P \rangle, \Gamma \)-model over \( X \) given by \( N_x = x \) for every \( x \in X \) satisfies a relational atom \( \rho \) if and only if there exist a clause \( \forall Y \cdot \land H \Rightarrow C \) in \( \Gamma \) and a substitution \( \psi: Y \rightarrow X \) such that \( \psi(C) = \rho \) and \( N \models_{\langle F, P \rangle,X} \land \psi(H) \).

Therefore, if \( \langle \langle F, P \rangle, \Gamma \rangle \models^*_{\langle F, P \rangle} \forall X \cdot \rho \), then \( N \models_{\langle F, P \rangle,X} \rho \), and thus there exists a clause \( \psi(\gamma) \in X(\Gamma) \) such that \( \rho, \psi(\gamma) \models_{\Sigma,X} \rho_1 \), where \( N \models_{\langle F, P \rangle,X} \rho_1 \).

By iterating this construction, we obtain an alternating sequence of \( X \)-queries and clauses as in **Definition 3.3.29**; furthermore, since \( N \models_{\langle F, P \rangle} \) is the free \( \langle F, P \rangle, \Gamma \)-model over \( X \), it is always possible to assemble such a sequence that terminates in a trivial query – which, in the case of \( \forall \mathcal{L}^1_{\omega} \), is simply the sentence \( \text{true} \) (see **Fact 3.3.21**). Consequently, \( \rho, X(\Gamma) \models^*_\Sigma,X \text{ true} \). A more detailed presentation of this result can be found, for example, in [Llo87].

**Proposition 3.3.33.** The logic-programming language \( (\forall \mathcal{L}^1_{\omega})_{\text{Pres}} \) of theory presentations over \( \forall \mathcal{L}^1_{\omega} \) is query-complete. \( \square \)

Our second lemma is now a direct consequence of **Proposition 3.3.30**.

**Lemma 3.3.34.** Suppose that \( \langle \Sigma, \Gamma \rangle \) is a query-complete logic program. Then for every \( \Sigma \)-query \( \exists X \cdot \rho \) such that \( X \) is conservative and \( \langle \Sigma, \Gamma \rangle \models^*_{\Sigma} \forall X \cdot \rho \), there exists a trivial query \( \exists X \cdot \top \) that can be derived from \( \exists X \cdot \rho \) and \( \Gamma \), with the identity substitution \( 1_X \) as the computed answer.

\[
\exists X \cdot \rho \rightarrow^*_{\Gamma,1_X} \exists X \cdot \top
\]

**Proof.** Let \( \langle \Sigma, \Gamma \rangle \) be a logic program as above and \( \exists X \cdot \rho \) a \( \Sigma \)-query such that \( \langle \Sigma, \Gamma \rangle \models^*_{\Sigma} \forall X \cdot \rho \). By query-completeness, there exists a trivial \( X \)-query \( \top \) such that \( \rho, X(\Gamma) \models^*_{\Sigma,X} \top \). Hence, by **Proposition 3.3.30**, we can derive the trivial query \( \exists X \cdot \top \) from \( \exists X \cdot \rho \) and \( \Gamma \) using the substitution \( 1_X \). \( \square \)
Theorem 3.3.35 (Completeness of resolution). Let \( \langle \Sigma, \Gamma \rangle \) be a query-complete logic program and \( \exists X \cdot \rho \) a \( \Sigma \)-query that admits an identity \( \forall X \cdot \gamma \in \Gamma \). Then every \( \langle \Sigma, \Gamma \rangle \)-solution to \( \exists X \cdot \rho \) is also a computed \( \langle \Sigma, \Gamma \rangle \)-answer to \( \exists X \cdot \rho \).

Proof. Let \( \psi : X \rightarrow Y \) be a \( \langle \Sigma, \Gamma \rangle \)-solution to \( \exists X \cdot \rho \). By Lemma 3.3.27, we know that \( \forall Y \cdot \psi(\rho) \) can be derived from \( \exists X \cdot \rho \) and its identity, \( \forall X \cdot \gamma \), using the substitution \( \psi \). Therefore, since \( \forall X \cdot \gamma \in \Gamma \), the query \( \forall Y \cdot \psi(\rho) \) can also be derived from \( \exists X \cdot \rho \) and \( \Gamma \).

\[
\exists X \cdot \rho \rightarrow_{\Gamma, \psi} \forall Y \cdot \psi(\rho)
\]

In addition, by Definition 3.3.8, the signature of variables \( Y \) is conservative, and \( \langle \Sigma, \Gamma \rangle \vdash_{\Sigma}^{lp} \forall Y \cdot \psi(\rho) \). Hence, by Lemma 3.3.34, we can derive a trivial query \( \exists Y \cdot \top \) from \( \forall Y \cdot \psi(\rho) \) and \( \Gamma \) using the computed substitution \( 1_Y \).

\[
\forall Y \cdot \psi(\rho) \rightarrow_{\Gamma, 1_Y}^{*} \exists Y \cdot \top
\]

Composing the two derivation chains outlined above yields a derivation of \( \exists Y \cdot \top \) from \( \exists X \cdot \rho \) using the substitution \( \psi \). Consequently, \( \psi \) is a computed answer to \( \exists X \cdot \rho \). \( \square \)
CONNECTION WITH INSTITUTIONS

This chapter is devoted to the formalization of the connection between the institution- and the substitution-system-based approach to logic programming. For this purpose, we investigate a number of features of institutions, like the existence of a quantification space or of representable substitutions, under which they give rise to suitable generalized substitution systems. Building on these results, we further show how the original institution-independent versions of Herbrand’s theorem can be obtained as concrete instances of the general result developed in Section 3.3.1.

Before we embark on the study of institution-based abstract logic-programming languages, let us briefly recall the logical systems that underlie two of the most prominent examples of (concrete) logic-programming languages examined in the context of institutions: first-order and higher-order equational logic programming [see e.g. GM86; Mes92; and also OPE97]. These will form the main reference points that we will use to illustrate the concepts and properties discussed in the subsequent sections of this chapter.

4.1 EQUATIONAL LOGIC PROGRAMMING

Equational logic programming integrates the machinery of its relational counterpart within algebraic specification in order to solve equations over abstract data types that are provided by given specifications. This is accomplished by replacing (a) the single-sorted relational variant of first-order logic (without equality) with the many-sorted equational variant of first-order logic (with equality) or with higher-order logic with Henkin semantics, (b) resolution with paramodulation, and (c) presentations (in the definition of logic programs) with program modules that are adequate for defining abstract data types. In this setting, the computation of the sum of $s \emptyset$ and $s \emptyset$ considered in Section 3.3 can be triggered by a query of the form

$$\frac{}{X_1 : \text{Nat}} s \emptyset + s \emptyset = X_1$$
meant to be solved over a logic program that consists of two modules: \texttt{NAT}, which defines natural numbers as an abstract data type, and \texttt{ADD}, which specifies the addition of natural numbers in the usual inductive manner.

\begin{verbatim}
module NAT = free
    sort Nat
    op @: → Nat
    op s_: Nat → Nat

module ADD = NAT then
    op _ +_: Nat Nat → Nat
    clause @ + M = M ↓ M: Nat
    clause (s M) + N = s (M + N) ↓ M,N: Nat
\end{verbatim}

\subsection{First-order equational logic}

First-order equational logic programming is defined over the institution \texttt{QFOL} of the quantifier-free fragment of many-sorted first-order equational logic. Since most of the definitions and properties to check are straightforward adaptations of the definitions and properties discussed in Section 3.1 for \texttt{QFOL} to the many-sorted equational setting of \texttt{QFOL}, we only shortly review some of the most important concepts that we need. A more in-depth discussion of the components of \texttt{QFOL} can be found, for example, in [GM87] or in the recent monographs [Dia08; ST11].

\textbf{Signatures.} The signatures of \texttt{QFOL} are pairs \(\langle S, F \rangle\) where \(S\) is a (finite) set of sorts and \(F\) is a family \((F_w)_{w \in S; s \in S}\) of (finite) sets of operation symbols indexed by arities and sorts. Signature morphisms \(\varphi: \langle S, F \rangle \to \langle S', F' \rangle\) are defined by functions \(\varphi^{\text{st}}: S \to S'\) between the sets of sorts and by families of functions \(\varphi^{\text{op}}_{w,:s}: F_{w,:s} \to F'_{\varphi^{\text{st}}(w),\varphi^{\text{st}}(s)}\) for \(w \in S'\) and \(s \in S\), between the sets of operation symbols.

\textbf{Sentences, models, and the satisfaction relation.} For every many-sorted signature \(\langle S, F \rangle\) and every sort \(s \in S\), the set \(T_{F,s}\) of \(F\)-terms of sort \(s\) is the least set such that \(\sigma(t_1, \ldots, t_n): s \in T_{F,s}\) for all \(\sigma \in F_{s_1,..,s_n \to s}\) and \(t_i \in T_{F,s_i}\). Similarly to the relational setting, the sentences over a \texttt{QFOL}-signature \(\langle S, F \rangle\) are built from equational atoms \(l = r\), where \(l\) and \(r\) are \(F\)-terms having the same sort, by iteration of the usual Boolean connectives.

\footnote{It should be noted that in [GM87] the authors consider a more general setting of order-sorted equational logic, with subsorts and overloading of operation symbols.}
The models, or algebras, $M$ of $(S, F)$ interpret each sort $s \in S$ as a set $M_s$, called the carrier set of $s$ in $M$, and each operation symbol $\sigma \in F_{s_1, \ldots, s_n \rightarrow s}$ as a function $M_\sigma : M_{s_1} \times \cdots \times M_{s_n} \rightarrow M_s$. Homomorphisms $h : M_1 \rightarrow M_2$ are families of functions $(h_\sigma : M_{1, \sigma} \rightarrow M_{2, \sigma})_{\sigma \in S}$ such that $h_\sigma(M_{1, \sigma}(m_1, \ldots, m_n)) = M_{2, \sigma}(h_\sigma(m_1), \ldots, h_\sigma(m_n))$ for all $\sigma \in F_{s_1, \ldots, s_n \rightarrow s}$ and $m_i \in M_{s_i}$.

$$
\begin{array}{c}
M_{1, s_1} \times \cdots \times M_{1, s_n} \xrightarrow{M_{1, \sigma}} M_{1, s} \\
\downarrow h_{s_1} \times \cdots \times h_{s_n} \\
M_{2, s_1} \times \cdots \times M_{2, s_n} \xrightarrow{M_{2, \sigma}} M_{2, s}
\end{array}
$$

Finally, the satisfaction relation is defined by induction on the structure of sentences, based on the evaluation of terms in models. For instance, an $(S, F)$-model $M$ satisfies an equational atom $l = r$ if and only $M_l = M_r$, that is if the terms $l$ and $r$ yield the same value in $M$.

### 4.1.2 Higher-Order Logic with Henkin Semantics

Building on the work of Russell on mathematical logic and the theory of types [see Ruso8], higher-order logic with Henkin semantics has been developed in [Chu40; Hen50] and later integrated into the framework of algebraic specifications in [MTW87]. As in [MTW87] and in more recent institution-theoretic works such as [ST11; Dia12b; Tuţ13] we use here a simplified version of higher-order logic that only takes into account $\lambda$-free terms. This does not limit its expressive power since for any term $\lambda(x : s). t$ we can define a new constant $\sigma$ and a universal sentence of the form $\forall x : S \cdot \sigma x = t$ – a detailed presentation of the encoding of higher-order logic with $\lambda$-abstraction into its $\lambda$-free subinstitution can be found in [Găi14].

Analogously to first-order equational logic programming, for the results presented in the following sections it suffices to consider the quantifier-free fragment of higher-order logic, whose institution we denote by $\mathcal{QF-HNK}$.

#### Signatures

A higher-order signature $(S, F)$ consists of a set $S$ of basic types, or sorts, and a family $(F_s)_{s \in \hat{S}}$ of sets of constant-operation symbols indexed by $S$-types, where $\hat{S}$ is the least set for which $S \subseteq \hat{S}$ and $s_1 \rightarrow s_2 \in \hat{S}$ whenever $s_1, s_2 \in \hat{S}$. Signature morphisms $\varphi : (S, F) \rightarrow (S', F')$ comprise functions $\varphi^{\text{id}} : S \rightarrow \hat{S}'$ and $\varphi^{\text{op}} : F_s \rightarrow F'_{\varphi^{\text{type}}(s)}$, for $s \in \hat{S}$, where $\varphi^{\text{type}} : \hat{S} \rightarrow \hat{S}'$ is the canonical extension of $\varphi^{\text{id}}$ given by $\varphi^{\text{type}}(s_1 \rightarrow s_2) = \varphi^{\text{type}}(s_1) \rightarrow \varphi^{\text{type}}(s_2)$.

---

2 Note that the universal sentences needed for encoding $\lambda$-terms can still be defined as Horn clauses of the logic programs under consideration.
SENTENCES, MODELS, AND THE SATISFACTION RELATION. Given a signature \( \langle S, F \rangle \), the family \( \langle T_{F,s} \rangle_{s \in S} \) of F-terms is the least family of sets such that 
\[
\sigma : s \in T_{F,s} \text{ for all types } s \in S \text{ and constants } \sigma \in F_s, \text{ and } (t_1) \in T_{F,s_1} \text{ for all terms } t_1 \in T_{F,s_1}, \text{ and } t_1 \in T_{F,s_1}. \text{ As in first-order logic, the sentences over } \langle S, F \rangle \text{ are built from equationally atoms } l = r, \text{ where } l \text{ and } r \text{ are terms in } T_{F,s} \text{ for some type } s \in S, \text{ by repeated applications of the Boolean connectives.}
\]

The models \( M \) of a higher-order signature \( \langle S, F \rangle \) interpret the types \( s \in S \) as sets \( M_s \), the constant symbols \( \sigma \in F_s \) as elements \( M_\sigma \in M_s \), and define injective maps \( \llbracket \_ \rrbracket^{M}_{s_1 \rightarrow s_2} : M_{s_1} \rightarrow [M_{s_1} \rightarrow M_{s_2}] \), where \( [M_{s_1} \rightarrow M_{s_2}] \) denotes the set of functions from \( M_{s_1} \) to \( M_{s_2} \) for any two types \( s_1, s_2 \in S \). Model homomorphisms \( h : M_1 \rightarrow M_2 \) are families of functions \( (h_s : M_{1,s} \rightarrow M_{2,s})_{s \in S} \) such that \( h_s(M_{1,\sigma}) = M_{2,\sigma} \) for every type \( s \in S \) and operation symbol \( \sigma \in F_s \), and the following diagram commutes for all \( s_1, s_2 \in S \) and \( f \in M_{1,s_1 \rightarrow s_2} \).

\[
\begin{align*}
M_{1,s_1} & \xrightarrow{\text{if}^{M}_{s_1 \rightarrow s_2}} M_{1,s_2} \\
& \downarrow h_{s_1} \\
M_{2,s_1} & \xrightarrow{\text{if}^{M}_{s_1 \rightarrow s_2}} M_{2,s_2} \\
& \downarrow h_{s_2}
\end{align*}
\]

The (inductive) definition of the satisfaction relation relies once again on the interpretation of terms in models, which extends the interpretation of constant-operation symbols as follows: for every \( \langle S, F \rangle \)-model \( M \) and every pair of terms \( t \in T_{F,s_1 \rightarrow s_2} \) and \( t_1 \in T_{F,s_1} \), \( M(t,t_1) = \llbracket M_{1} \rrbracket^{M}_{s_1 \rightarrow s_2}(M_{1}) \).

4.2 INSTITUTION-INDEPENDENT SUBSTITUTIONS

The institution-independent concept of substitution [see Dia04; and also Dia08] generalizes first-order substitutions (as well as second-order and higher-order substitutions, among others) to arbitrary institutions by taking notice only of their syntactic and semantic effects: the translations of sentences and the reductions of models that they generate. A key step in arriving at this notion is the presentation of the extensions of signatures by sets of variables as particular cases of signature morphisms (along the lines of [ST84]).

Thus, given two signature morphisms \( \chi_1 : \Sigma \rightarrow \Sigma_1 \) and \( \chi_2 : \Sigma \rightarrow \Sigma_2 \) (two extensions of a signature \( \Sigma \)) in an institution \( J = \langle \text{Sig}, \text{Sen}, \text{Mod}, \_ \rangle \), a substitution \( \psi : \chi_1 \rightarrow \chi_2 \) is a pair \( \langle \text{Sen}_\Sigma(\psi), \text{Mod}_\Sigma(\psi) \rangle \) consisting of

- a sentence-translation function \( \text{Sen}_\Sigma(\psi) : \text{Sen}(\Sigma_1) \rightarrow \text{Sen}(\Sigma_2) \) and
- a model-reduction functor \( \text{Mod}_\Sigma(\psi) : \text{Mod}(\Sigma_2) \rightarrow \text{Mod}(\Sigma_1) \)
that preserve \( \Sigma \), in the sense that \( \text{Sen}(\chi_1) \models \text{Sen}_\Sigma(\psi) = \text{Sen}(\chi_2) \) and \( \text{Mod}_\Sigma(\psi) \models \text{Mod}(\chi_1) = \text{Mod}(\chi_2) \), and satisfy the following condition:

\[
M_2 \models \Sigma \text{Sen}_\Sigma(\psi)(\rho_1) \quad \text{if and only if} \quad \text{Mod}_\Sigma(\psi)(M_2) \models \Sigma_1 \rho_1
\]

for every \( \Sigma_2 \)-model \( M_2 \) and every \( \Sigma_1 \)-sentence \( \rho_1 \).

In the present work, we take into consideration an equivalent formulation of the original definition that makes use of the category \( \text{Room} \) of rooms and corridors. In addition, we extend the fact that substitutions inherit the composition of their components – thus giving rise to a category – to derive a general substitution system of \( \Sigma \)-substitutions for each signature \( \Sigma \).

**Proposition 4.2.1.** Let \( \Omega \subseteq \text{Sig} \) be a class of signature morphisms of an institution \( \mathcal{I} \colon \text{Sig} \to \text{Room} \). For every \( \mathcal{I} \)-signature \( \Sigma \) we obtain a substitution system \( \mathcal{S}_\mathcal{I}^\Omega_\Sigma \colon \text{Subst}_\mathcal{I}^\Omega_\Sigma \to \mathcal{I}(\Sigma) / \text{Room} \) defined as follows:

- The objects of the category \( \text{Subst}_\mathcal{I}^\Omega_\Sigma \) – i.e. the signatures of \( \Sigma \)-variables – are signature morphisms \( \chi \colon \Sigma \to \Sigma(\chi) \) belonging to the class \( \Omega \). Their corresponding corridors via the functor \( \mathcal{S}_\mathcal{I}^\Omega_\Sigma \) are given simply by \( \mathcal{I}(\chi) \colon \mathcal{I}(\Sigma) \to \mathcal{I}(\Sigma(\chi)) \).
- For every two signatures of \( \Sigma \)-variables \( \chi_1 \colon \Sigma \to \Sigma(\chi_1) \) and \( \chi_2 \colon \Sigma \to \Sigma(\chi_2) \), a \( \Sigma \)-substitution \( \psi \colon \chi_1 \to \chi_2 \) consists of a corridor \( \langle \text{Sen}_\Sigma(\psi), \text{Mod}_\Sigma(\psi) \rangle \) between \( \mathcal{I}(\Sigma(\chi_1)) \) and \( \mathcal{I}(\Sigma(\chi_2)) \) such that \( \mathcal{I}(\Sigma(\chi_1)) \models \langle \text{Sen}_\Sigma(\psi), \text{Mod}_\Sigma(\psi) \rangle = \mathcal{I}(\Sigma(\chi_2)) \).

As such, \( \Sigma \)-substitutions are merely arrows in the comma category \( \mathcal{I}(\Sigma) / \text{Room} \), meaning that they are identified with their images under the functor \( \mathcal{S}_\mathcal{I}^\Omega_\Sigma \). The composition of substitutions is defined accordingly.

**Example 4.2.2.** In \( \text{FOL}_\Sigma \), a first-order variable over a signature \( \langle S, F \rangle \) is a triple \( \langle x, s, F_{\varepsilon \to s} \rangle \),\(^4\) often denoted simply by \( x : s \), where \( x \) is the name of the variable and \( s \) is its sort. Thus, \( \text{FOL}_\Sigma \)-signatures of \( \langle S, F \rangle \)-variables \( X \) are \( S \)-indexed families of sets \( X_s \) of variables of sort \( s \) such that different variables have different names. First-order substitutions \( \psi \colon X \to Y \) can be

---

3 For convenience, we denote the codomain of the signature morphism \( \chi \) by \( \Sigma(\chi) \); this reflects the intuition that \( \Sigma(\chi) \) is an extension of the signature \( \Sigma \) with variables defined by \( \chi \).

4 We denote the empty arity by \( \varepsilon \); hence, \( F_{\varepsilon \to s} \) is the set of \( F \)-constants of sort \( s \).
further defined as $S$-indexed families of maps $\psi_s : X_s \to T_{F \cup Y, s}$ that assign a term over the extended signature $\langle S, F \cup Y \rangle$ to every variable of $X$.

One can easily check that every first-order substitution $\psi : X \to Y$ gives rise to a general substitution between the inclusions $\langle S, F \rangle \subseteq \langle S, F \cup X \rangle$ and $\langle S, F \rangle \subseteq \langle S, F \cup Y \rangle$, much the same as in the case of $\mathbf{qFOL}_1$ [see e.g. Dia08]. For instance, the reduct $\text{Mod}_{\langle S, F \rangle}(\psi)(N)$ of an $\langle S, F \cup Y \rangle$-model $N$ is the $\langle S, F \cup X \rangle$-expansion of $N\upharpoonright_{\langle S, F \rangle}$ given by $\text{Mod}_{\langle S, F \rangle}(\psi)(N)_{x : s} = N_{\psi(x)}$ for every variable $x : s$ of $X$. Note, however, that not every general substitution between $\langle S, F \rangle \subseteq \langle S, F \cup X \rangle$ and $\langle S, F \rangle \subseteq \langle S, F \cup Y \rangle$ corresponds to a first-order substitution; we will discuss this aspect to a greater extent in Section 4.3.2.

Higher-order signatures of variables and substitutions can be defined likewise, by recalling that a higher-order variable over a signature $\langle S, F \rangle$ is a triple of the form $(x, s, F_s)$, where $x$ and $s$ correspond to the name and the type of the variable [see e.g. Ţuţ13; and also Codo7]. As expected, this means that we allow higher-order variables to range over arbitrary functions.

4.3 QUANTIFICATION SPACES

Due to its mild assumptions, the construction outlined in Proposition 4.2.1 cannot be easily generalized to accommodate signature morphisms. More precisely, one cannot guarantee that signature morphisms $\varphi : \Sigma \to \Sigma'$ determine adequate morphisms between the substitution systems associated with $\Sigma$ and $\Sigma'$: it would suffice, for example, to consider a class $\mathcal{Q}$ of signature morphisms that consists only of extensions of $\Sigma$, thus preventing the translation of the signatures of $\Sigma$-variables along $\varphi$. To overcome this limitation, we take into account only those extensions of signatures that belong to a quantification space – a notion introduced in [Dia10] in the context of quasi-Boolean encodings5 and utilized in a series of papers on hybridization and many-valued institutions [see e.g. Mar+11; Dia13b; Dia13a].

Quantification spaces provide a way of translating signatures of variables along signature morphism by means of dedicated pushout constructions. For the purpose of our work, it will be convenient to consider a more categorical formulation of the original definition, based on Fact 4.3.1 below.

**Fact 4.3.1.** Consider a category $\mathbb{K}$ and a subcategory $\mathcal{Q}$ of the category $\mathbb{K}^\rightarrow$ of $\mathbb{K}$-arrows. The domain functor $\text{dom} : \mathcal{Q} \to \mathbb{K}$ gives rise to a natural transformation $\downarrow_\mathcal{Q} : \downarrow / \mathcal{Q} \Rightarrow \text{dom}^{\text{op}} \downarrow / \mathbb{K}$ where, for every triple $\langle A_1, f, A_2 \rangle$ in

---

5 It should be noted, however, that the ideas that underlie quantification spaces can be traced back to [Tar86; ST88a] – two of the earliest works in which open formulae are treated in arbitrary institutions.
|Q| (i.e. arrow \( f : A_1 \to A_2 \) in \( \mathbb{K} \)), \( \iota_Q: f/Q \to A_1/\mathbb{K} \) is the functor that maps the morphisms \( (g_1, g_2) : (A_1, f, A_2) \to (A_1', f', A_2') \) in \( Q \) (corresponding to commutative squares in \( \mathbb{K} \)) to \( g_1: A_1 \to A_1' \).

\[
\begin{array}{ccc}
A_1 & \xrightarrow{\xi_1} & A_1' \\
\downarrow f & & \downarrow f' \\
A_2 & \xrightarrow{\xi_2} & A_2'
\end{array}
\]

\[ A_1 \xrightarrow{\xi_1} A_1' \quad \xrightarrow{\phi, \phi} \quad A_1 \xrightarrow{\xi_1} A_1' \]

**Definition 4.3.2** (Quantification space). A quantification space for an institution \( J: \text{Sig} \to \text{Room} \) consists of a subcategory \( Q \) of \( \text{Sig}^* \) such that

1. every arrow in \( Q \) corresponds to a pushout in \( \text{Sig} \), and
2. the transformation \( \iota_Q: (\_ / Q) \Rightarrow \text{dom}^{op} (\_ / \text{Sig}) \) is a natural isomorphism.

This means that for every extension of signatures \( \chi: \Sigma \to \Sigma'(\chi) \) in \( |Q| \) and every signature morphism \( \varphi: \Sigma \to \Sigma' \) there exist a unique extension \( \chi': \Sigma' \to \Sigma'(\chi') \) in \( |Q| \) and a unique signature morphism \( \phi: \Sigma(\chi) \to \Sigma'(\chi') \) such that the pair \( (\varphi, \phi) \) defines a morphism in \( Q \) between the arrows \( \chi \) and \( \chi' \). We will henceforth denote the signature extension \( \chi' \) and the signature morphism \( \phi \) by \( \chi^\varphi: \Sigma' \to \Sigma'(\chi^\varphi) \) and \( \varphi^\chi: \Sigma(\chi) \to \Sigma'(\chi^\varphi) \), respectively.

\[
\begin{array}{ccc}
\Sigma & \xrightarrow{\varphi} & \Sigma' \\
\downarrow \chi & & \downarrow \chi^\varphi \\
\Sigma(\chi) & \xrightarrow{\varphi^\chi} & \Sigma'(\chi^\varphi)
\end{array}
\]

**Example 4.3.3**. For both \( \varphi\text{-FOL}_n \) and \( \varphi\text{-HNK} \), the extensions of signatures \( \chi: \langle S, F \rangle \to \langle S, F \cup X \rangle \) defined by (families of) finite sets of first-order/higher-order \( \langle S, F \rangle \)-variables \( X \) form a quantification space. More precisely, for every signature morphism \( \varphi: \langle S, F \rangle \to \langle S', F' \rangle \),

- \( \chi^\varphi: \langle S', F' \rangle \to \langle S', F' \cup X^\varphi \rangle \) is the extension of \( \langle S', F' \rangle \) given by \( X^\varphi = \{ x : s' \mid x: s \in X_s \text{ for some sort } s \in S \text{ (or type } s \in \tilde{S} \text{) such that }\varphi(s) = s' \} \), and
- \( \varphi^\chi: \langle S, F \cup X \rangle \to \langle S', F' \cup X^\varphi \rangle \) is the canonical extension of \( \varphi \) that maps each \( \langle S, F \rangle \)-variable \( x : s \in X \) to the \( \langle S', F' \rangle \)-variable \( x: \varphi(s) \) in \( X^\varphi \).

**Definition 4.3.4** (Adequacy). For any institution, a quantification space \( Q \) is said to be adequate if every arrow \( \langle \varphi, \varphi^\chi \rangle: \chi \to \chi^\varphi \) in \( Q \) corresponds to a model-amalgamation square: for every \( \Sigma' \)-model \( M' \) and \( \Sigma(\chi) \)-model
\( N \) such that \( M' \models \varphi = N \models \chi \) there exists a unique model \( N' \) of \( \Sigma'(\chi^\varphi) \) – the \textit{amalgamation} of \( M' \) and \( N \) – such that \( N' \models \chi^\varphi = M' \) and \( N' \models_{\varphi}s = N \).

In semi-exact institutions\(^7\) – like \( qfFOL \) [see Mes89; DGS93] – all quantification spaces are adequate. This is not the case of \( qfHNK \), for which it is known that, due to the presence of higher-order types, not every pushout square of signature morphisms is a model-amalgamation square [see e.g. Codo7]. Nonetheless, the quantification space for \( qfHNK \) outlined in Example 4.3.3 is adequate: the amalgamation \( N' \) of any two given models \( M' \) of \( \langle S', F' \rangle \) and \( N \) of \( \langle S, F \cup X \rangle \) is the unique \( \chi^\varphi \)-expansion of \( M' \) that satisfies
\[
N' \models_{\varphi}s = N \models_{s} \text{ for each variable } x : s \text{ in } X.
\]

\textbf{Remark 4.3.5.} Since the morphisms of any quantification space \( Q \) are required to form a category (by definition, \( Q \) is a subcategory of \( \text{Sig}^- \)), for every signature extension \( \chi : \Sigma \to \Sigma(\chi) \) in \( Q \) and every pair of composable signature morphisms \( \varphi : \Sigma \to \Sigma' \) and \( \varphi' : \Sigma' \to \Sigma'' \), we have \( (\chi^\varphi)^{\varphi'} = \chi^{\varphi \varphi'} \) and \( \varphi^\chi_{\chi'} (\varphi')^\chi = (\varphi^\chi \varphi')^\chi \). Moreover, \( \chi_{\Sigma} = \chi \) and \( 1_{\Sigma} = 1_{\Sigma(\chi)} \).

\[
\begin{array}{c}
\Sigma \\
\xymatrix{
\Sigma(\chi) \ar[r]^{\chi^\varphi} & \Sigma' \ar[r]^{\varphi'} & \Sigma'' \ar[l]_{(\chi^\varphi)^{\varphi'}} \\
\Sigma(\chi) \ar[u]_{\chi} \ar[r]^{\varphi^\chi} & \Sigma'(\chi^\varphi) \ar[r]_{(\varphi^\chi)^{\varphi'}} & \Sigma''((\chi^\varphi)^{\varphi'}) \\
& (\varphi^\chi \varphi')^\chi \\
}
\end{array}
\]

Quantification spaces thus provide adequate support for translating abstract signature extensions along morphisms of signatures in a functorial manner.

4.3.1 \textbf{REPRESENTABLE SIGNATURE EXTENSIONS}

Since the institution-independent substitutions of Proposition 4.2.1 correspond to a semantic concept, we cannot expect to translate them along signature morphisms in the same manner as the extensions of signatures provided by a given quantification space. The solution that we propose herein relies on an important characterization of the first-order signature extensions with variables (regarded as new constant-operation symbols): for every \( qfFOL \)-signature extension \( \langle S, F \rangle \subseteq \langle S, F \cup X \rangle \) there is a one-to-one correspondence between the models of \( \langle S, F \cup X \rangle \) and the model homomorphisms defined on the free \( \langle S, F \rangle \)-algebra \( T_F(X) \) over the set of variables \( X \); in particular, every \( \langle S, F \cup X \rangle \)-model \( N \) determines the homomorphism

\[^7\] We recall that an institution is semi-exact – in the sense of [Mes89; DGS93] – if its model functor preserves pullbacks.
$h: T_F(X) \to N \upharpoonright_{\langle S, F \rangle}$ given by $h(x) = N_x$ for every variable $x$ in $X$. In this context, $T_F(X)$ is said to be a \textit{representation} of the inclusion of signatures $\langle S, F \rangle \subseteq \langle S, F \cup X \rangle$. The following definition originates from [Dia03].

**Definition 4.3.6** (Representable signature morphism). In any institution, a signature morphism $\chi: \Sigma \to \Sigma(\chi)$ is \textit{representable} if there exist a $\Sigma$-model $M_\chi$, called the \textit{representation} of $\chi$, and an isomorphism of categories $i_\chi$ between $\text{Mod}(\Sigma(\chi))$ and $M_\chi / \text{Mod}(\Sigma)$ such that the following diagram commutes.

$\begin{array}{ccc}
\text{Mod}(\Sigma) & \xrightarrow{i_\chi} & M_\chi / \text{Mod}(\Sigma) \\
\downarrow{l_{\Sigma}} & & \downarrow{l_{M_\chi}} \\
\text{Mod}(\Sigma(\chi)) & \xrightarrow{l_{\Sigma(\chi)}} & M_\chi / \text{Mod}(\Sigma(\chi))
\end{array}$

Representable first-order signature morphisms were studied in depth in [Şer04], from where we recall Proposition 4.3.7 below [see also Dia08].

**Proposition 4.3.7.** A first-order signature morphism is representable if and only if it is bijective on all symbols. □

Consequently, for every $\sigma$-$\text{FOL}$-signature $\langle S, F \rangle$, all signature extensions $\langle S, F \rangle \subseteq \langle S, F \cup X \rangle$ given by finite sets $X$ of $\langle S, F \rangle$-variables are representable.

A similar result can be obtained for $\sigma$-$\text{HNK}$. In that case, however, the signature extensions with constants $\langle S, F \rangle \subseteq \langle S, F \cup X \rangle$ can only be guaranteed to be quasi-representable, in the sense that, for every $\langle S, F \cup X \rangle$-model $N$, the canonical functor $N / \text{Mod}(S, F \cup X) \to N \upharpoonright_{\langle S, F \cup X \rangle} / \text{Mod}(S, F)$ determined by the model-reduct functor $\downarrow{l_{\langle S, F \rangle}}$ is an isomorphism (see e.g. [Cod07] for more details). Representability further requires that the resulting higher-order signatures $\langle S, F \cup X \rangle$ have initial models, a property which holds whenever $\langle S, F \cup X \rangle$ has at least one constant-operation symbol for each type.⁸

**Proposition 4.3.8.** All higher-order signature extensions $\langle S, F \rangle \subseteq \langle S, F \cup X \rangle$ with (finite) sets $X$ of new constant-operation symbols are representable, provided that $F_s \cup X_s \neq \emptyset$ for each type $s \in \vec{S}$. □

**Remark 4.3.9.** Let $\chi: \Sigma \to \Sigma(\chi)$ and $\chi': \Sigma' \to \Sigma'(\chi')$ be a pair of representable signature extensions defined by a quantification space $Q$, and let $\beta$ and

---

⁸ This property is commonly achieved by assuming that, for each type $s \in \vec{S}$, the set $F_s$ contains an implicit constant-operation symbol.
\(\beta'\) be two functors as depicted below such that \(\text{Mod}(\chi') \circ \beta = \beta' \circ \text{Mod}(\chi)\).

\[
\begin{array}{ccc}
\text{Mod}(\Sigma) & \xrightarrow{\beta} & \text{Mod}(\Sigma') \\
\downarrow_{\text{id}} & & \downarrow_{\text{id}} \\
\text{Mod}(\Sigma(\chi)) & \xrightarrow{\beta'} & \text{Mod}(\Sigma'(\chi'))
\end{array}
\]

The composition \(i_{\chi}^{-1} \circ \beta' \circ i_{\chi}\) gives rise to a functor \(U\) between the comma categories \(M_{\chi'} / \text{Mod}(\Sigma')\) and \(M_{\chi} / \text{Mod}(\Sigma)\), where

- for every \(\Sigma'\)-model homomorphism \(h': M_{\chi'} \to M'\), \(U(h')\) is the \(\Sigma\)-model homomorphism \((i_{\chi}^{-1} \circ \beta' \circ i_{\chi})(h')\): \(M_{\chi} \to \beta(M')\), and
- for every arrow \(f': h'_1 \to h'_2\) between model homomorphisms \(h'_1: M_{\chi'} \to M'_1\) and \(h'_2: M_{\chi'} \to M'_2\), \(U(f')\) is just the \(\beta\)-reduct of \(f'\), \(\beta(f'): \beta(M'_1) \to \beta(M'_2)\).

When \(\beta\) corresponds to the model-reduct functor \(\text{Mod}(\phi)\) of a signature morphism \(\phi: \Sigma \to \Sigma'\), and when \(\chi'\) and \(\beta'\) are \(\chi'\) and \(\text{Mod}(\phi^{-1})\), respectively, we will denote the functor \(U: M_{\chi'} / \text{Mod}(\Sigma') \to M_{\chi} / \text{Mod}(\Sigma)\) by \(U_{\phi,\chi}\).

Similarly, when \(\beta\) is the identity of \(\text{Mod}(\Sigma)\) and \(\beta'\) is the underlying model functor of a substitution \(\psi: \chi \to \chi'\), we will denote the functor \(U\) by \(U_\psi\).

Model homomorphisms \(h': M_{\chi'} \to M'\) can be regarded both as objects and as arrows (between \(1_{M_{\chi'}}\) and \(h'\)) in the comma category \(M_{\chi'} / \text{Mod}(\Sigma')\). In combination with the definition of \(U: M_{\chi'} / \text{Mod}(\Sigma') \to M_{\chi} / \text{Mod}(\Sigma)\), the arrow view provides us a useful factorization of \(U(h')\) as \(U(1_{M_{\chi'}}) \circ \beta(h')\).

\[
\begin{array}{ccc}
M_{\chi'} & \xrightarrow{h'} & M' \\
\downarrow_{1_{M_{\chi'}}} & & \downarrow_{U(h')} \\
M_{\chi'} & \xrightarrow{U(1_{M_{\chi'}})} & M' \\
\downarrow_{\beta(h')} & & \downarrow_{\beta(M')} \\
\beta(M_{\chi'}) & \xrightarrow{U(h')} & \beta(M')
\end{array}
\]

**Fact 4.3.10.** Under the notation and hypotheses of Remark 4.3.9, for every \(\Sigma'\)-model homomorphism \(h': M_{\chi'} \to M'\), \(U(h') = U(1_{M_{\chi'}}) \circ \beta(h')\).

### 4.3.2 Representable Substitutions

Quantification spaces that have representable extensions of signatures, meaning that every extension \(\chi: \Sigma \to \Sigma(\chi)\) defined by the quantification space is representable, allow us to extend the concept of representability from signature extensions (i.e. signatures of variables) to substitutions, leading to a purely model-theoretic view of the categories of substitutions.
**Proposition 4.3.11.** For every signature $\Sigma$ in an institution equipped with a quantification space $Q$, the representation of the extensions of signatures extends to a functor $R_Q^\Sigma : \text{Subst}^Q_\Sigma \rightarrow \text{Mod}(\Sigma)$, where

- for every extension of signatures $\chi : \Sigma \rightarrow (\chi)\text{ in } Q, R_Q^\Sigma(\chi) = M_\chi$, and
- for every substitution $\psi : \chi_1 \rightarrow \chi_2, R_Q^\Sigma(\psi) = U\psi(1_{M_{\chi_1}}) ; M_{\chi_1} \rightarrow M_{\chi_2}$.

Moreover, for any $\Sigma$-substitution $\psi, \text{Mod}^\Sigma(\psi)$ is uniquely determined by $R_Q^\Sigma(\psi)$.

**Proof.** The preservation of composition follows from a series of straightforward calculations based on the fact that, for every pair $\Sigma$-substitutions $\psi_1 : \chi_1 \rightarrow \chi_2$ and $\psi_2 : \chi_2 \rightarrow \chi_3, \text{Mod}^\Sigma(\psi_1 \otimes \psi_2) = \text{Mod}^\Sigma(\psi_2) \circ \text{Mod}^\Sigma(\psi_1)$.

\[
R_Q^\Sigma(\psi_1 \otimes \psi_2) = U\psi_1(1_{M_{\chi_3}}) = (i_{\chi_3}^{-1} \circ \text{Mod}^\Sigma(\psi_1) \circ i_{\chi_3})(1_{M_{\chi_3}}) = (i_{\chi_3}^{-1} \circ \text{Mod}^\Sigma(\psi_2) \circ i_{\chi_2})(1_{M_{\chi_3}}) = (i_{\chi_3}^{-1} \circ \text{Mod}^\Sigma(\psi_1) \circ i_{\chi_1})(1_{M_{\chi_3}}) = U\psi_1(U\psi_2(1_{M_{\chi_3}})) = R_Q^\Sigma(\psi_1) \circ R_Q^\Sigma(\psi_2)
\]

In much the same way, based on the fact that $\text{Mod}^\Sigma(1_\chi) = 1_{\text{Mod}(\Sigma(\chi))}$, for every signature of $\Sigma$-variables $\chi : \Sigma \rightarrow (\chi), we obtain $R_Q^\Sigma(1_\chi) = 1_{M_\chi}$.

To prove the second part of the statement, notice that by the definition of $U\psi$, we have $\text{Mod}^\Sigma(\psi) = i_{\chi_2} \circ U\psi \circ i_{\chi_1}^{-1}$, where $\chi_1$ and $\chi_2$ correspond to the domain and codomain signatures of variables of the substitution $\psi$. This allows us to deduce, based on Fact 4.3.10, that $\text{Mod}^\Sigma(\psi)(N_2) = i_{\chi_1}^{-1}(U\psi(i_{\chi_2}(N_2))) = i_{\chi_1}^{-1}(U\psi(1_{M_{\chi_2}} \circ i_{\chi_2}(N_2))) = i_{\chi_1}^{-1}(R_Q^\Sigma(\psi) \circ i_{\chi_2}(N_2))$ for every model $N_2$ of $\Sigma(\chi_2)$. Furthermore, by Remark 4.3.9, the reduction of $\Sigma(\chi_2)$-model homomorphisms $h_2$ is given by $\text{Mod}^\Sigma(\psi)(h_2) = i_{\chi_1}^{-1}(i_{\chi_2}(h_2))$. Therefore, for any substitution $\psi' : \chi_1 \rightarrow \chi_2$ such that $R_Q^\Sigma(\psi') = R_Q^\Sigma(\psi), \text{Mod}^\Sigma(\psi') = \text{Mod}^\Sigma(\psi)$. \qed

When the quantification space $Q$ and the signature $\Sigma$ are clear from the context (as well as the institution under consideration), we may also denote the representation $R_Q^\Sigma(\psi)$ of a substitution $\psi : \chi_1 \rightarrow \chi_2$ by $h_\psi : M_{\chi_1} \rightarrow M_{\chi_2}$.

Note that, in general, the functor $R_Q^\Sigma : \text{Subst}^Q_\Sigma \rightarrow \text{Mod}(\Sigma)$ of Proposition 4.3.11 need be neither full nor faithful. For example, in the case of
\(qF_{\text{FOL}}\), for every general substitution \(\psi\) we can define another substitution \(\psi'\) (with the same domain and codomain as \(\psi\)) such that, for every atomic sentence \(l = r\) that is not ground, \(\text{Sen}_\Sigma(\psi')(l = r)\) corresponds to \(\text{Sen}_\Sigma(\psi)(r = l)\). In consequence, we can obtain distinct institution-independent substitutions having the same underlying model functor – and thus, the same representation. This is contrary to our intuition concerning first-order substitutions, where, given a signature \(\langle S, F \rangle\), every substitution \(\psi' : \chi_1 \to \chi_2\), i.e. every \(S\)-indexed family of maps \(\psi_s : X_{1,s} \to T_{F \cup X_{2,s}}\), is determined uniquely by its representation \(R^Q_{\langle S, F \rangle}(\psi) : T_F(X_1) \to T_F(X_2)\). As we will see later, the full and faithful representation of substitutions as model homomorphisms is essential for translating substitutions along signature morphisms.

**Definition 4.3.12** (Representable substitution). Let \(\Sigma\) be a signature in an institution equipped with a quantification space \(Q\). For every subcategory \(\text{Subst}_\Sigma \subseteq \text{Subst}^Q_\Sigma\), a substitution \(\psi : \chi_1 \to \chi_2\) in \(\text{Subst}_\Sigma\) is said to be \(Q\)-representable if it is uniquely determined by its image under \(R^Q_\Sigma\). In addition, \(\text{Subst}_\Sigma\) forms a category of \(Q\)-representable \(\Sigma\)-substitutions if the restriction of the functor \(R^Q_\Sigma : \text{Subst}^Q_\Sigma \to \text{Mod}(\Sigma)\) to \(\text{Subst}_\Sigma\) is both full and faithful.

**Example 4.3.13.** Let \(Q\) be the quantification space for \(qF_{\text{FOL}}\) presented in Example 4.3.3. For every first-order signature \(\langle S, F \rangle\), the subcategory \(\text{Subst}_{\langle S, F \rangle} \subseteq \text{Subst}^Q_{\langle S, F \rangle}\) whose arrows correspond to the corridors induced by first-order substitution forms a category of \(Q\)-representable substitutions. A similar property can be formulated for higher-order substitutions.

For the remaining part of this chapter we will assume that \(\Sigma\) is an arbitrary but fixed institution \(\langle \Sigma, \text{Sen}, \text{Mod}, \text{F} \rangle\) equipped with

- an adequate quantification space \(Q \subseteq \Sigma^+\) of representable signature extensions,
- a broad subcategory \(\text{Subst}_\Sigma \subseteq \text{Subst}^Q_\Sigma\) (i.e. with the same objects as \(\text{Subst}^Q_\Sigma\)), for every signature \(\Sigma\in|\Sigma|\), of \(Q\)-representable \(\Sigma\)-substitutions.

**Lemma 4.3.14.** Under the above assumptions, for every morphism \(\varphi : \Sigma \to \Sigma'\) in \(\Sigma\) and every signature extension \(\chi : \Sigma \to \Sigma(\chi)\) in \(|Q|\), the homomorphism

\(U_{\varphi, \chi}(1_{M_{\chi}^\psi}) : M_\chi \to M_{\chi'}^\varphi\)

is a universal arrow from \(M_\chi\) to \(\text{Mod}(\varphi)\).

**Proof.** Suppose that \(h : M_\chi \to M'_{\varphi}^\psi\) is a \(\Sigma\)-model homomorphism from \(M_\chi\) to the reduct of a \(\Sigma'\)-model \(M'\). Since \(\chi\) is representable, we know that \(i_{\chi}^{-1}(h)^\chi = M'_{\varphi}\). This allows us to deduce, based on the adequacy of \(Q\), that there exists a unique \(\Sigma'(\chi^\psi)'\)-model \(N'\) satisfying \(N'_{\chi^\psi} = M'\) and \(N'_{\chi^\psi} = i_{\chi}^{-1}(h)\). We thus obtain the homomorphism \(i_{\chi^\psi}(N') : M_{\chi^\psi} \to M'\).
To show that $\U_{\psi,\chi}(1_{M_\psi}) \downarrow i_\psi(N') \uparrow \varphi = h$, and thus that $i_\psi(N') \uparrow \varphi$ is an arrow in $M_\chi$ modulo (Σ) between $\U_{\psi,\chi}(1_{M_\psi})$ and $h$, it suffices to consider $i_\psi(N')$ as an arrow in $M_\chi$ modulo (Σ) between $1_{M_\psi}$ and $i_\psi(N')$. In this way, by taking the image of $i_\psi(N')$ under $\U_{\psi,\chi}$, we obtain the arrow $i_\psi(N') \uparrow \varphi$ between $\U_{\psi,\chi}(1_{M_\psi})$ and $\U_{\psi,\chi}(i_\psi(N')) = i_\psi(N') \uparrow \varphi$.

For the ‘uniqueness’ part of the universality of $\U_{\psi,\chi}(1_{M_\psi})$, let $f'$ be an arbitrary $\Sigma'$-homomorphism $M_\chi \rightarrow M'$ such that $\U_{\psi,\chi}(1_{M_\psi}) \downarrow f' \uparrow \varphi = h$. Then $i_{\chi}^{-1}(f')$ is a $\Sigma'(\chi')$-model and, in addition, it satisfies $i_{\chi}^{-1}(f') \uparrow \psi = M'$ and $i_{\chi}^{-1}(f') \uparrow \chi = i_\chi^{-1}(h)$; the latter equality follows from the observation that $\chi(i_{\chi}^{-1}(f') \uparrow \psi) = \U_{\psi,\chi}(f') = \U_{\psi,\chi}(1_{M_\psi}) \downarrow f' \uparrow \varphi = h$. Therefore, $i_{\chi}^{-1}(f')$ is the amalgamation of $M'$ and $i_\chi^{-1}(h)$; this further implies that $i_{\chi}^{-1}(f') = N'$, because $Q$ is adequate, thus allowing us to conclude that $f' = i_\psi(N')$. □

The lemma above enables us to make use of a well-known construction of adjoint functors from universal arrows [see e.g. AHS9] to derive translations between categories of substitutions. We thus obtain the following result.

**Proposition 4.3.15.** Every morphism of signatures $\varphi : \Sigma \rightarrow \Sigma'$ gives rise to a functor $\Psi_\varphi : \text{Subst}_\Sigma \rightarrow \text{Subst}_{\Sigma'}$ that maps

\[
\begin{array}{ccc}
\mathcal{J}(\Sigma) & \xrightarrow{\varphi} & \mathcal{J}(\Sigma') \\
\mathcal{J}(\chi_1) & \xrightarrow{\varphi|_{\chi_1}} & \mathcal{J}(\chi_1') \\
\mathcal{J}(\chi_2) & \xrightarrow{\varphi|_{\chi_2}} & \mathcal{J}(\chi_2') \\
\mathcal{J}(\Sigma(\chi_1)) & \xrightarrow{\varphi} & \mathcal{J}(\Sigma'(\chi_1')) \\
\mathcal{J}(\Sigma(\chi_2)) & \xrightarrow{\varphi} & \mathcal{J}(\Sigma'(\chi_2')) \\
\end{array}
\]

- every signature extension $\chi : \Sigma \rightarrow \Sigma(\chi)$ to $\chi' : \Sigma' \rightarrow \Sigma'(\chi')$, and
- every $\Sigma$-substitution $\psi : \chi_1 \rightarrow \chi_2$ to $\psi^\varphi = (R^Q_{\Sigma'})^{-1}(h^\varphi_{\psi})$, where $h^\varphi_{\psi}$ is the unique $\Sigma'$-homomorphism $1_{M_{\chi_1}} \rightarrow M_{\chi_2}^\varphi$ for which the diagram below commutes.

\[
\begin{array}{ccc}
M_{\chi_1} & \xrightarrow{\U_{\psi,\chi}(1_{M_{\chi_1}^\varphi})} & M_{\chi_1}^\varphi \uparrow \varphi \\
M_{\chi_2} & \xrightarrow{\U_{\psi,\chi}(1_{M_{\chi_2}^\varphi})} & M_{\chi_2}^\varphi \uparrow \varphi \\
\end{array}
\]
Moreover, \( \Psi \) itself is functorial, in the sense that \( \Psi_{\varphi\varphi'} = \Psi_{\varphi} \circ \Psi_{\varphi'} \) for every composable signature morphisms \( \varphi: \Sigma \to \Sigma' \) and \( \varphi': \Sigma' \to \Sigma'' \), and \( \Psi_{1_{\Sigma}} = 1_{\text{Subst}_{\Sigma}} \).

**Proof.** The first part of the statement follows by Lemma 4.3.14 as a direct consequence of the universal property of the homomorphism \( U_{\varphi, \chi} : (1_{M_1^Q}) \) – note that, since the functor \( R^Q_{\Sigma} \) is assumed to be both full and faithful, for every signature \( \Sigma \), it suffices to reason about the representations of substitutions. With respect to the second part of the statement, notice first that, by the definition of quantification spaces, the translation of signature extensions along signature morphisms is functorial (see Remark 4.3.5). In addition, by Remark 4.3.9, for every signature extension \( \chi: \Sigma \to \Sigma(\chi) \), \( U_{\varphi_{\varphi}', \chi} = U_{\varphi_{\varphi}', \chi} \circ U_{\varphi_{\chi}} \). This allows us to deduce, according to Fact 4.3.10, that \( U_{\varphi_{\varphi}', \chi}(1_{M_1^Q}) = U_{\varphi_{\chi}}(1_{M_1^Q}) \circ U_{\varphi_{\varphi}'}(1_{M_1^Q}) \). Hence, by the general properties of composing universal arrows, we can further conclude that the translation of substitutions along signature morphisms is also functorial. \( \square \)

### 4.3.3 Deriving Generalized Substitution Systems

For any signature morphism \( \varphi: \Sigma \to \Sigma' \), the functor \( \Psi_{\varphi}: \text{Subst}_{\Sigma} \to \text{Subst}_{\Sigma'} \) discussed in Proposition 4.3.15 can be extended in a straightforward manner to a morphism \( (\Psi_{\varphi}, \kappa_{\varphi}, \tau_{\varphi}) \) between the substitution systems \( S_{\Sigma} \) and \( S_{\Sigma'} \) obtained by restricting the functors \( S^Q_{\Sigma} \) and \( S^Q_{\Sigma'} \) of Proposition 4.2.1 to the subcategories \( \text{Subst}_{\Sigma} \) and \( \text{Subst}_{\Sigma'} \) of \( \Sigma \)- and \( \Sigma' \)-substitutions.

\[
\begin{array}{ccc}
\text{Subst}_{\Sigma} & \xrightarrow{S_{\Sigma}} & \mathcal{I}(\Sigma) / \text{Room} \\
\Psi_{\varphi} & \downarrow & \downarrow T_{\varphi} \\
\text{Subst}_{\Sigma'} & \xrightarrow{S_{\Sigma'}} & \mathcal{I}(\Sigma') / \text{Room}
\end{array}
\]

To be more specific, \( \kappa_{\varphi} \) is the corridor \( (\text{Sen}(\varphi), \text{Mod}(\varphi)) \) obtained by taking the image \( \mathcal{I}(\varphi) \) of \( \varphi \) under the institution \( \mathcal{I} \), regarded as a functor into \( \text{Room} \). Furthermore, for every signature extension \( \chi: \Sigma \to \Sigma(\chi) \), the corridor \( \tau_{\varphi, \chi}: \mathcal{I}(\Sigma(\chi)) \to \mathcal{I}(\Sigma'(\chi^\delta)) \) is simply \( \mathcal{I}(\varphi^\chi) \). It should be noted, however, that the naturality of \( \tau_{\varphi} \) holds in general only up to semantic equivalence (see Proposition 4.3.16 below): this means that we can only guarantee that \( \text{Mod}(\varphi^\chi) \) is natural in \( \chi \), and thus that, for every substitution \( \psi: \chi_1 \to \chi_2 \) and sentence \( \rho \) over \( \Sigma(\chi_1) \), \( \varphi^{\chi_2}(\psi(\rho)) \equiv \psi^\varphi(\varphi^{\chi_1}(\rho)) \).

In concrete cases like \( \varphi_{\text{FOL}_c} \), the equality \( \varphi^{\chi_2}(\psi(\rho)) = \psi^\varphi(\varphi^{\chi_1}(\rho)) \) is usually due to the careful choice of the categories of substitutions; other choices, which may involve,

---

9 We recall that two sentences \( p_1 \) and \( p_2 \) are semantically equivalent, denoted \( p_1 \equiv p_2 \), if and only if they are satisfied by the same class of models.
for example, swapping the left- and the right-hand side of non-ground equational atoms, do not necessarily give rise to natural transformations $\tau_\varphi$. For this reason, in what follows, we will implicitly assume that the categories $\text{Subst}_\Sigma$ of $\Sigma$-substitutions are \textit{compatible} with respect to signature morphisms, meaning that $\psi \circ J(\varphi^\Sigma) = J(\varphi^\chi) \circ \psi^\varphi$ for every substitution $\psi : \chi_1 \to \chi_2$.

**Proposition 4.3.16.** For every signature morphism $\varphi : \Sigma \to \Sigma'$ and every $\Sigma$-substitution $\psi : \chi_1 \to \chi_2$, $\text{Mod}(\varphi^\chi\chi) \circ \text{Mod}(\psi) = \text{Mod}(\varphi^\chi) \circ \text{Mod}(\psi^\chi)$.  

**Proof.** The conclusion follows easily by ‘chasing’ the diagram bellow, provided that the outer square is commutative, that is $U_{\varphi,\chi} \circ U_\psi = U_{\varphi^\psi} \circ U_{\varphi,\chi_1}$.

\[
\begin{array}{c}
\text{Mod}(\Sigma) \xrightarrow{i_{\chi_1}} \text{Mod}(\Sigma(\chi_1)) \xleftarrow{-1_{\varphi}} \text{Mod}(\Sigma'(\chi_1^\varphi)) \xrightarrow{i_{\chi_1}^\psi} M_{\chi_1} \xrightarrow{\varphi^\chi} \text{Mod}(\Sigma') \\
U_\psi \downarrow \quad \downarrow -1_\varphi \quad \downarrow -1_{\varphi^\psi} \quad \downarrow \quad \downarrow U_{\varphi^\chi} \\
\text{Mod}(\Sigma) \xrightarrow{i_{\chi_2}} \text{Mod}(\Sigma(\chi_2)) \xleftarrow{-1_{\varphi}} \text{Mod}(\Sigma'(\chi_2^\varphi)) \xrightarrow{i_{\chi_2}^\psi} M_{\chi_2} \xrightarrow{\varphi^\chi} \text{Mod}(\Sigma') \\
U_\psi \downarrow \quad \downarrow -1_{\varphi^\psi} \quad \downarrow \quad \downarrow U_{\varphi^\chi}
\end{array}
\]

This equality can also be established without difficulty by noticing that, for every $\Sigma'$-homomorphism $h' : M_{\chi_2} \to M'$,

\[
(U_{\varphi,\chi_2} \circ U_\psi)(h') = h_\varphi \circ U_{\varphi,\chi_2}(1_{M_{\chi_2}^\psi}) \circ h' \circ 1_\varphi \quad \text{by Fact 4.3.10 and Proposition 4.3.11} \\
= U_{\varphi,\chi_2}(1_{M_{\chi_2}^\psi}) \circ h_\varphi \circ 1_\varphi \circ h' \circ 1_\varphi \quad \text{by Proposition 4.3.15} \\
= (U_{\varphi^\psi} \circ U_{\varphi,\chi_1})(h') \quad \text{by Fact 4.3.10 and Proposition 4.3.11}
\]

Analogously, for every arrow $f'$ in the comma category $M_{\chi_2}^\psi \circ \text{Mod}(\Sigma')$, one can check directly that $(U_{\varphi,\chi_2} \circ U_\psi)(f') = f' \circ h'. 
\]

We can now conclude the construction of a generalized substitution system $\mathcal{S} J : \text{Sig} \to \text{SubstSys}$ from an arbitrary institution $J : \text{Sig} \to \text{Room}$ that satisfies the hypotheses laid out in \textbf{Section 4.3.2} by noticing that, according to \textbf{Proposition 4.3.15}, to the fact that $J$ is a functor, and to \textbf{Remark 4.3.5}, all components of the morphism of substitution systems $\langle \Psi_\varphi, \kappa_\varphi, \tau_\varphi \rangle$ presented above are functorial in $\varphi$. Moreover, since the quantification space of $J$ is assumed to be adequate, the generalized substitution system $\mathcal{S} J$ has model amalgamation. This leads us to the first main result of the present chapter.
**Theorem 4.3.17.** For any institution $\mathcal{I}: \text{Sig} \to \text{Room}$ equipped with an adequate quantification space $Q$ of representable signature extensions and with compatible categories $\text{Subst}_\Sigma$ of $Q$-representable $\Sigma$-substitutions, $\mathcal{S}I: \text{Sig} \to \text{SubstSys}$ is a generalized substitution system that has model amalgamation. □

**Example 4.3.18.** Both institutions $\text{qF}_\text{OL}_\Sigma$ and $\text{qF}_\text{HNK}_\Sigma$ in combination with signature extensions with constants and with the first-order and higher-order substitutions outlined in Example 4.2.2, give rise to generalized substitution systems, which we will denote by $\text{qF}_\text{OL}_\Sigma$ and $\text{qF}_\text{HNK}_\Sigma$ respectively.

### 4.4 Logic Programming over an Arbitrary Institution

The view we take here is that the logic programming paradigm can be developed over an arbitrary institution $\mathcal{I}: \text{Sig} \to \text{Room}$ by considering logic-programming frameworks and languages defined over the generalized substitution system $\mathcal{S}I: \text{Sig} \to \text{SubstSys}$ introduced in Section 4.3.3. To this end, we assume that $\mathcal{I}: \text{Sig} \to \text{Room}$ is an institution that satisfies the hypotheses of Theorem 4.3.17, and we let $\mathcal{L}$ be a logic-programming language $\langle \text{LP}, \text{Sign}, \text{PMod}, \text{Ax} \rangle$ defined over a framework $\langle \mathcal{S}I, \mathcal{C}, Q, \vdash \rangle$. Since the underlying generalized substitution system of $\mathcal{L}$ is derived from $\mathcal{I}$, it is often more convenient – especially when discussing concrete examples – to regard $\mathcal{C}$ and $Q$ as subfunctors of the sentence functor $\text{Sen}: \text{Sig} \to \text{Set}$ of $\mathcal{I}$.

#### 4.4.1 Paramodulation

Paramodulation originated with the work of Robinson and Wos [RW83] as a refinement of resolution that is suitable for dealing with clauses and queries defined over first-order logic with equality. The definition of its corresponding goal-directed rules relies on the following notions of context and substitution of a term in a given context [see e.g. ST11; and also BN99].

For any sort $s$ of a first-order signature $\langle S, F \rangle$ – and similarly, for any type $s$ of a higher-order signature $\langle S, F \rangle$ – a context for $s$ is a term $c$ over an extended signature of the form $\langle S, F \cup \{\square : s\} \rangle$ that contains precisely one occurrence of the new variable $\square$. The substitution of a term $t \in T_{F,s}$ in $c$, denoted $c[t]$, is defined simply as the translation of $c$ along the substitution ($\square \mapsto t$): $\{\square : s\} \to \emptyset$ that maps $\square$ to the term $t$.

**Clauses and Queries.** For every signature $\langle S, F \rangle$ – and, in particular, for signature extensions with constants $\langle S, F \cup X \rangle$ – the local (quantifier-free) clauses are defined, as in the relational case, as implications of the form...
where \( H \Rightarrow (l = r) \), where \( H \) is a finite set of equational atoms and \( l = r \) is an equational atom. In a similar manner, the local queries over \( \langle S, F \rangle \) are just finite conjunctions \( \bigwedge Q \) of equational atoms.

**Goal-directed rules.** (Local) paramodulation is given by rules of the form

\[
\bigwedge (\{c[l] = t\} \cup Q), \bigwedge H \Rightarrow (l = r) \vdash_{(S,F \cup X)} \bigwedge (\{c[r] = t\} \cup Q \cup H)
\]
or

\[
\bigwedge (\{l = c[l]\} \cup Q), \bigwedge H \Rightarrow (l = r) \vdash_{(S,F \cup X)} \bigwedge (\{t = c[r]\} \cup Q \cup H)
\]

where \( \langle S, F \rangle \subseteq \langle S, F \cup X \rangle \) is a signature extension with constants, \( Q \) and \( H \) are finite sets of atoms over \( \langle S, F \cup X \rangle \), \( l \) and \( r \) are \( (F \cup X) \)-terms of some sort \( s \), \( c \) is a context for \( s \), and \( t \) is an \( (F \cup X) \)-term with the same sort as \( c \).

It is easy to verify that the above constructions satisfy all the necessary properties of Definition 3.3.2, thus giving rise to two logic-programming frameworks: \( \forall \mathcal{L}_e \) – over (many-sorted) first-order equational logic – and \( \forall \mathcal{N} \mathcal{K} \) – over higher-order equational logic. Moreover, the abstract concept of resolution captures in this setting an extended version of what is known as paramodulation: a query \( \exists X_2 \cdot \bigwedge Q_2 \) (over some signature \( \langle S, F \rangle \)) is derived by paramodulation in one step from another query \( \exists X_1 \cdot \bigwedge Q_1 \) and a clause \( \forall Y_1 \cdot \bigwedge H_1 \Rightarrow (l_1 = r_1) \) using the computed substitution \( \theta_1 : X_1 \rightarrow X_2 \) if and only if there exists a substitution \( \psi_1 : Y_1 \rightarrow X_2 \) such that

\[
\bigwedge \theta_1(Q_1), (\bigwedge \psi_1(H_1) \Rightarrow (\psi_1^{\text{lm}}(l_1) = \psi_1^{\text{lm}}(r_1))) \vdash_{(S,F \cup X_2)} \bigwedge Q_2.
\]

The extension is in this case twofold: first, the derivation is not limited to most general unifiers (similarly to the relational variant of logic programming); second, the term \( \psi_1^{\text{lm}}(l_1) \) need not be equal with the \( \theta_1 \)-translation of a subterm in \( Q_1 \), but with a subterm in the \( \theta_1 \)-translation of \( Q_1 \).

**Computation answer.** All that is needed now in order to compute answers to queries defined over \( \forall \mathcal{L}_e \) or \( \forall \mathcal{N} \mathcal{K} \) is an analogue of Fact 3.3.21 providing an adequate characterization of trivial queries. To this end, notice that a first-order signature extension with constants \( \langle S, F \rangle \subseteq \langle S, F \cup X \rangle \) is conservative if and only if there exists at least one \( F \)-term for each sort \( s \in S \) such that \( T_{F \cup X,s} \) is not empty. A similar property holds in general for higher-order logic because we assumed that all signatures of interest have at least one constant-operation symbol for each type. Hence, all higher-order signature extensions with constants that we consider here are conservative.

**Fact 4.4.1.** Let \( \langle S, F \rangle \subseteq \langle S, F \cup Y \rangle \) be a \( \forall \mathcal{L}_e \)-signature extension such that
\( T_{\emptyset, s} = \emptyset \) implies \( T_{\emptyset, s} = \emptyset \) for every \( s \in S \). Then an \( \langle S, F \rangle \)-query \( \exists Y \cdot T \) is trivial if and only if \( T \) is a conjunction of equalities of the form \( t = t \).

To illustrate the use of paramodulation, let \( \Gamma \) be the set that consists of the two clauses defined by the module \( \text{ADD} \) together with the identity clause \( \forall \emptyset \cdot \text{true} \Rightarrow (\emptyset = \emptyset) \). Then the sum of \( s \emptyset \) and \( s \emptyset \) can be computed according to the following chain of derivations:

\[
\exists \{ X_1 : \text{Nat} \} \cdot s \emptyset + s \emptyset = X_1
\]

\[\rightarrow_{\Gamma, X_1 \rightarrow X_2} \exists \{ X_2 : \text{Nat} \} \cdot s (\emptyset + s \emptyset) = X_2\]

using the second clause of \( \Gamma \) and the substitution \( M \mapsto s \emptyset \)

\[\rightarrow_{\Gamma, X_2 \rightarrow X_3} \exists \{ X_3 : \text{Nat} \} \cdot s s \emptyset = X_3\]

using the first clause of \( \Gamma \) and the substitution \( M \mapsto s \emptyset \)

\[\rightarrow_{\Gamma, X_3 \rightarrow s s \emptyset} \exists \emptyset \cdot s s \emptyset = s s \emptyset.\]

using the third (and last) clause

### 4.4.2 Herbrand’s Theorem Revisited

Under the additional assumption that, for every signature \( \Sigma \), the identity \( 1_\Sigma \) is a signature of variables – the ‘empty’ signature of \( \Sigma \)-variables – the general institution-independent versions of Herbrand’s theorem presented in [Dio04; Dio08] can be obtained as more concrete instances of Theorem 3.3.13. In particular, the equivalence \( 1 \iff 2 \) of Theorem 4.4.5 captures the denotational aspect of Herbrand’s theorem – how the problem of checking whether a logic program entails a given query can be reduced from all models of the program to those that are initial; on the other hand, the equivalence \( 2 \iff 3 \) emphasizes the operational aspect of the theorem – the correspondence between those expansions of the program’s initial model that satisfy the underlying (quantifier-free) sentence of the query and the possible solutions to the query, about which we know that can be computed when properties such as query-completeness are satisfied (see Theorem 3.3.35).

To start with, let us recall that, in any category, an object \( A \) is said to be projective with respect to an arrow \( e : B \to C \) provided that every arrow \( f : A \to C \) can be factored through \( e \) as \( f = h \circ e \), for some arrow \( h : A \to B \). For instance, as a consequence of the axiom of choice, for every \( \text{FOL}_{\Sigma} \)-signature extension \( \langle S, F \rangle \subseteq \langle S, F \cup X \rangle \), the free algebra \( T_{\emptyset}(X) \) – the representation of the inclusion \( \langle S, F \rangle \subseteq \langle S, F \cup X \rangle \) – is projective with respect to all epimorphisms, and in particular with respect to all quotient homomorphisms \( 0_{\langle S, F \rangle} \rightarrow 0_{\langle S, F \rangle}\Gamma \) that correspond to sets of \( \langle S, F \rangle \)-clauses \( \Gamma \).

The concept of basic sentence [see Dio03; and also Tar86, where it was studied under the name of ground positive elementary sentence] captures categorically the satisfaction of the conjunctions of atomic sentences that are usually involved in defining logic-programming queries.
**Definition 4.4.2** (Basic sentence). For any signature $\Sigma$, a sentence $\rho$ is said to be basic if there exists a model $M_\rho$ such that, for every $\Sigma$-model $M$, $M \models \rho$ if and only if there exists a model homomorphism $M_\rho \to M$.

**Example 4.4.3.** In the institution $\text{qr-}\text{FOL}_\omega$, every (finite) conjunction $\bigwedge E$ of first-order equational atoms forms a basic sentence [see e.g. Dia08]. This property does not hold in general for $\text{qr-}\text{HNK}$, for which one can define higher-order equational atoms of the form $\sigma_1 f = \sigma_2 f$, with $f : s \to s$ and $\sigma_1, \sigma_2 : (s \to s) \to s'$, that are not basic [see Codo7; Dia08].

We also recall from [Dia03] the following immediate result.

**Fact 4.4.4.** For any signature $\Sigma$, the satisfaction of basic sentences is preserved by all $\Sigma$-model homomorphisms: for every basic sentence $\rho$ and model homomorphism $h : M_1 \to M_2$ such that $M_1 \models \rho$, $M_2 \models \rho$.

The above preliminaries enable us to recast the institution-independent versions of Herbrand’s theorem in the context of (institution-based) abstract logic-programming languages.

**Theorem 4.4.5.** Consider a logic program $\langle \Sigma, \Gamma \rangle$ and a $\Sigma$-query $\exists X \cdot \rho$ such that

- both the signature $\Sigma$ and the program $\langle \Sigma, \Gamma \rangle$ have initial models $0_\Sigma$ and $0_{\langle \Sigma, \Gamma \rangle}$,
- $M_X$ is projective with respect to the unique homomorphism $!_\Gamma : 0_\Sigma \to 0_{\langle \Sigma, \Gamma \rangle}$, and
- the $\Sigma(X)$-sentence $\rho$ is basic.

Then the following statements are equivalent:

1. $\langle \Sigma, \Gamma \rangle \models_{\Sigma} \exists X \cdot \rho$.
2. $0_{\langle \Sigma, \Gamma \rangle} \models_{\Sigma} \exists X \cdot \rho$.
3. $\exists X \cdot \rho$ admits a $\langle \Sigma, \Gamma \rangle$-solution.

**Proof.** According to Theorem 3.3.13, it suffices to show that $0_{\langle \Sigma, \Gamma \rangle}$ is $\chi$-reachable and that the satisfaction of $\rho$ is preserved by $\chi$-homomorphisms. The latter property is guaranteed by Fact 4.4.4, because $\rho$ is basic. Therefore, we will focus solely on proving that $0_{\langle \Sigma, \Gamma \rangle}$ is $\chi$-reachable.

Let $N_{\langle \Sigma, \Gamma \rangle}$ be a $\chi$-expansion of $0_{\langle \Sigma, \Gamma \rangle}$. Since $\chi$ is a representable extension of signatures (by hypothesis), we know that $i_\chi (N_{\langle \Sigma, \Gamma \rangle}) : M_X \to 0_{\langle \Sigma, \Gamma \rangle}$ is an object of the comma category $M_X / \text{Mod}(\Sigma)$; and because its representation, $M_X$, is projective with respect to $!_\Gamma : 0_\Sigma \to 0_{\langle \Sigma, \Gamma \rangle}$, it follows that there exists a $\Sigma$-model homomorphism $h : M_X \to 0_\Sigma$ such that $h \downarrow !_\Gamma = i_\chi (N_{\langle \Sigma, \Gamma \rangle})$.

\[
\begin{array}{ccc}
M_X & \xrightarrow{h} & 0_\Sigma \\
\downarrow i_\chi (N_{\langle \Sigma, \Gamma \rangle}) & \searrow !_\Gamma \\
0_{\langle \Sigma, \Gamma \rangle} & & \\
\end{array}
\]
Moreover, since the identity $1\Sigma$ is a signature of $\Sigma$-variables – which, by hypothesis, is also representable – we deduce that $0\Sigma$ is (isomorphic to) the representation $M_{1\Sigma}$ of $1\Sigma$. By the representability of $\Sigma$-substitutions, we further obtain the substitution $(R^Q_\Sigma)^{-1}(h) : \chi \rightarrow 1\Sigma$, which we will henceforth denote by $\psi$. All we need to prove now is that the canonical map $\_\Sigma : N_{\Sigma,\Gamma} / \Mod_\Sigma(\psi) \rightarrow 0_{\Sigma,\Gamma} / \Mod(\Sigma)$ is surjective on objects.

To this end, notice that every $\Sigma$-model homomorphism $g : 0_{\Sigma,\Gamma} \rightarrow M$ can be viewed as an arrow in $M_\chi / \Mod(\Sigma)$ between $i_\chi(N_{\Sigma,\Gamma})$ and $i_\chi(N_{\Sigma,\Gamma}) \triangleright g$, from which we deduce that $i_\chi^{-1}(g)$ is a $\Sigma(\chi)$-model homomorphism between $N_{\Sigma,\Gamma}$ and $N = i_\chi^{-1}(i_\chi(N_{\Sigma,\Gamma}) \triangleright g)$. In addition, by Proposition 4.3.11 and the commutativity of the diagram below, we obtain $M_\Sigma |_{\psi} = i_\chi^{-1}(h \triangleright !_M) = i_\chi^{-1}(i_\chi(N_{\Sigma,\Gamma}) \triangleright g) = N$, thus confirming that $i_\chi^{-1}(g) : N_{\Sigma,\Gamma} \rightarrow M_\Sigma |_{\psi}$ is an object of $N_{\Sigma,\Gamma} / \Mod_\Sigma(\psi)$. The conclusion of the theorem follows by observing that $N_\Sigma |_{\chi} = \_i_\chi(N_{\Sigma,\Gamma}) \triangleright g |_{M_\Sigma} = M$ and $i_\chi^{-1}(g) |_{\Sigma} = g |_{M_\Sigma} = g$.

\[
\begin{array}{ccc}
M_\chi & \xrightarrow{h} & 0\Sigma \\
\downarrow i_\chi(N_{\Sigma,\Gamma}) & & \downarrow i_\chi(N_{\Sigma,\Gamma}) \\
0_{\Sigma,\Gamma} & \xrightarrow{g} & M \\
\end{array}
\]
A LOGIC-PROGRAMMING SEMANTICS OF SERVICES

Building on recent theoretical advancements in the algebraic structures that capture the way services are orchestrated and in the processes that formalize the discovery and binding of services to given client applications by means of logical representations of required and provided services, in the following we develop formal foundations for notions and mechanisms needed to support service-oriented computing. In particular, we show how the denotational and the operational semantics specific to conventional logic programming can be generalized using the theory presented in Chapter 3 to address both static and dynamic aspects of services, thus leading to a service-oriented variant of the paradigm. Our results rely upon a strong analogy between the discovery of a service that can be bound to an application and the search for a clause that can be used for computing an answer to a query; they explore the manner in which requests for external services can be described as service queries, and explain how the computation of their answers can be performed through service-oriented derivatives of unification and resolution, which characterize the binding of services and the reconfiguration of applications.

5.1 ORCHESTRATION SCHEMES

The first step in the development of the particular variant of logic programming that we consider in this chapter consists in determining appropriate categorical abstractions of the structures that support service-oriented computing. These will ultimately allow us to describe the process of service discovery and binding in a way that is independent of any particular formalism (like various forms of automata, transition systems, or process algebras).

Our approach is grounded on two observations: first, that orchestrations can be organized as a category whose arrows, or more precisely, cospans of arrows, can be used to model the composition of service components (as defined, for example, in [FLB07; FLB11; FL13a]); second, that the discovery
of a service module to be bound to a given application can be formalized in terms of logical specifications of required and provided services, ensuring that the specification of the provided service refines the specification of the requested service. To this end, we explore the model-theoretic notion of refinement advanced in [ST88b], except that, in the present setting, the structures over which specifications are evaluated are morphisms into ground orchestrations, that is into orchestrations that have no dependencies on external services. The motivation for this choice is that, in general, the semantics of non-ground orchestrations is open: the (observable) behaviour exhibited by non-ground orchestrations varies according to the external services that they may procure at run time. With these remarks in mind, we arrive at the following concept of orchestration scheme.

**Definition 5.1.1** (Orchestration scheme). An orchestration scheme is a quadruple \( O = (\text{Orc}, \text{Spec}, \text{Grc}, \text{Prop}) \) consisting of

- a category \( \text{Orc} \) of orchestrations and orchestration morphisms,
- a functor \( \text{Spec} : \text{Orc} \to \text{Set} \) defining, for every orchestration \( o \), the set \( \text{Spec}(o) \) of service specifications over \( o \),
- a full subcategory \( \text{Grc} \subseteq \text{Orc} \) of ground orchestrations, and
- a functor \( \text{Prop} : \text{Grc} \to \text{Set} \) defining, for every ground orchestration \( g \), the natural subset \( \text{Prop}(g) \subseteq \text{Spec}(g) \) of properties of \( g \) (specifications that are guaranteed to hold when evaluated over \( g \)).

To illustrate our categorical approach to orchestrations, we consider two main running examples: program expressions as discussed in [Fia12; see also Morg94], which provide a way of constructing structured (sequential) programs through design-time discovery and binding, and the theory of asynchronous relational networks put forward in [FL13b], which emphasizes the role of services as an interface mechanism for software components that can be composed through run-time discovery and binding.

### 5.1.1 Program Expressions

The view that program expressions can be seen as defining ‘service orchestrations’ through which structured programs can be built in a compositional way originates from [Fia12]. Intuitively, we can see the rules of the Hoare calculus [see Hoa69] as defining ‘clauses’ in the sense of logic programming, where unification is controlled through the refinement of pre/post-

\[\text{Prop}(g) \subseteq \text{Spec}(g)\]  

\[\text{Prop}(g) \subseteq \text{Spec}(g)\]  

1 By describing \( \text{Prop}(g) \) as a natural subset of \( \text{Spec}(g) \) we mean that the family of inclusions \( \{\text{Prop}(g) \subseteq \text{Spec}(g)\}_g \) defines a natural transformation from \( \text{Prop} \to (\text{Grc} \subseteq \text{Orc}) \Rightarrow \text{Spec} \).
conditions as specifications of provided/required services, and resolution binds program statements (terms) to variables in program expressions.

In Figure 5.1, we depict Hoare rules in a notation that is closer to that of service modules, which also brings out their clausal form: the specification (a pair of a pre- and a post-condition) on the left-hand side corresponds to the consequent of the clause (which relates to a ‘provides-point’ of the service), while those on the right-hand side correspond to the antecedent of the clause (i.e. to the ‘requires-points’ of the service) – the specifications of what remains to be discovered and bound to the program expression (the ‘service orchestration’ inside the box) to produce a program. In Figure 5.2, we retrace Hoare’s original example of constructing a program that computes the quotient and the remainder resulting from the division of two natural numbers as an instance of the unification and resolution mechanisms particular to logic programming. We will further discuss these mechanisms in more detail in Section 5.2.3.

\[\rho, \rho \] skip

(assignment)

\[\rho(e), \rho(x) \] \(x := e\)

(sequence)

if \(C\) then
\[\rho, \rho'\]
otherwise
\[\rho, \rho''\]
endif

while \(C\) do
\[\rho, \rho \land \neg[C], \rho'\]
done

The formal description of program expressions that we consider here follows the presentation given in [GM96] of the algebraic semantics of programs, except that, instead of the theory of many-sorted algebra, we rely on the theory of preordered algebra developed in [DF98], whose institution we denote by \(\text{POA}\). In this context, signatures are ordinary algebraic signatures.
The derivation of a program that computes the quotient \( q \) and the remainder \( r \) obtained from the division of \( x \) by \( y \):

\[ x = q \cdot y + r \]

- **SP1**: \( x = q \cdot y + r \)
- **SP2**: \( x = q \cdot y + r \)
- **SP3**: \( x = q \cdot y + r \)
- **SP4**: \( x = q \cdot y + r \)
- **SP5**: \( x = q \cdot y + r \)
- **SP6**: \( x = q \cdot y + r \)
- **SP7**: \( x = q \cdot y + r \)
- **SP8**: \( x = q \cdot y + r \)
- **SP9**: \( x = q \cdot y + r \)
- **SP10**: \( x = q \cdot y + r \)
- **SP11**: \( x = q \cdot y + r \)
- **SP12**: \( x = q \cdot y + r \)
- **SP13**: \( x = q \cdot y + r \)
- **SP14**: \( x = q \cdot y + r \)
- **SP15**: \( x = q \cdot y + r \)
- **SP16**: \( x = q \cdot y + r \)

---

**Figure 5.2**
whose denotation is defined over the category of preorders rather than that of sets, with models interpreting the sorts as preordered sets and the operation symbols as monotonic functions. The sentences are built as in first-order logic based on two kinds of atoms: equational atoms \( l = r \) and preorder atoms (transitions) \( l \rightarrow r \), where \( l \) and \( r \) are terms of the same sort; the latter are satisfied by a preordered algebra \( A \) if and only if the interpretations of \( l \) and \( r \) in \( A \) belong to the preorder relation of the carrier of their sort.

In order to fully define the orchestration scheme of program expressions we assume that the programming language we have chosen to analyse is specified through a many-sorted signature \( \langle S, F \rangle \) equipped with

- a distinguished set of sorts \( S_{pgm} \subset S \) corresponding to the types of executable expressions supported by the language, and sorts \( State, Config \in S \setminus S_{pgm} \) capturing the states of the programs and the various configurations that may arise upon their execution, respectively;
- operation symbols \( \langle \_ \rangle : State \rightarrow Config \) and \( \langle \_, \_ \rangle : eXp \; State \rightarrow Config \), for \( eXp \in S_{pgm} \), which we regard as constructor operators for the sort \( Config \);
- a (sortwise infinite) \( S_{pgm} \)-indexed set \( Var \) of program variables together with state variables \( st, st' : State \), used to refer to the states that precede or result from executions; and
- a preordered \( (S, F) \)-algebra \( A \) that describes the semantics of the programming language through the preorder relation associated with the sort \( Config \). \(^2\)

**Example 5.1.2.** The premises that we consider within this section are weak enough to allow the proposed algebraic framework to accommodate a wide variety of programming languages. For instance, the program expressions underlying the modules depicted in Figure 5.1 are simply terms of sort \( Pgm \) that can be formed based on the following five operation symbols (written using the mixfix notation of CAFEOBJ [DFQ8] and CASL [Mos04]):

\[
\begin{align*}
\text{(empty statement)} & \quad \text{skip}: \rightarrow Pgm, \\
\text{(assignment)} & \quad \_ := \_ : \text{Id} \; \text{AExp} \rightarrow Pgm, \\
\text{(sequence)} & \quad \_ \; ; \_ : Pgm \; Pgm \rightarrow Pgm, \\
\text{(selection)} & \quad \text{if} \; \_ \; \text{then} \; \_ \; \text{else} \; \_ \; \text{endif} : \text{Cond} \; Pgm \rightarrow Pgm, \\
\text{(iteration)} & \quad \text{while} \; \_ \; \text{do} \; \_ \; \text{done} : \text{Cond} \; Pgm \rightarrow Pgm.
\end{align*}
\]

In this case, the many-sorted signature of interest can be described as follows:

- Besides the sort \( Pgm \) of program expressions, the set \( S \) also comprises the

\(^2\) Alternatively, one could use a theory presentation or a structured specification instead of \( A \).
sorts $\text{Id}$ of identifiers, $\text{AExp}$ of arithmetic expressions, and $\text{Cond}$ of conditions, as well as the two essential sorts $\text{State}$ and $\text{Config}$.

- The operation symbols in $F$ are those that correspond to the five types of program expressions presented above (empty statement, assignment, sequence, selection, and iteration) together with the usual operation symbols associated with identifiers (like $\_ : \text{Id} \to \text{AExp}$, which is used to denote the value bound to a given identifier), with the addition, subtraction and multiplication of arithmetic expressions, and with the atoms and Boolean connectives specific to conditions. In addition, $F$ also contains the two operation symbols $\langle \_ \rangle : \text{State} \to \text{Config}$ and $\langle \_ , \_ \rangle : \text{Pgm State} \to \text{Config}$.

The only expressions considered to be executable are those of sort $\text{Pgm}$, hence $S^{\text{Pgm}}$ is just the singleton set $\{\text{Pgm}\}$. Furthermore, the obvious candidates for $\text{State}$ and $\text{Config}$ are the sorts $\text{State}$ and $\text{Config}$, and a similar observation can be stated for the operation symbols $\langle \_ \rangle$ and $\langle \_ , \_ \rangle$. As for the preordered algebra $A$ that defines the semantics of the programming language, we note that, apart from $\text{State}$ and $\text{Config}$, the interpretations of sorts and operation symbols are straightforward. With respect to states, the carrier $A_{\text{State}}$ can be regarded simply as the discrete preorder of partial functions from identifiers to values (natural numbers). Based on this, we can define configurations (elements of sort $\text{Config}$) either as plain states, corresponding to those configurations that are considered to be ‘final’, or as pairs $\langle \text{Pgm}, \text{St} \rangle$, which indicate the start of the execution of a program expression $\text{Pgm}$ in a state $\text{St}$. Finally, the transitions between such configurations can be defined using natural operational-semantics rules as in [Kah87]: for instance, for any two program expressions $\text{Pgm}_1$ and $\text{Pgm}_2$, and any two states $\text{St}_1$ and $\text{St}_2$, if there exists a transition $\langle \text{Pgm}_1, \text{St}_1 \rangle \to \langle \text{St}_2 \rangle$, then there exists a transition $\langle \text{Pgm}_1 \circ \text{Pgm}_2, \text{St}_1 \rangle \to \langle \text{Pgm}_2, \text{St}_2 \rangle$ as well.

Algebraic signatures having the aforementioned additional structure induce orchestration schemes in a canonical way, as follows.

**Orchestrations.** The orchestrations are program expressions, that is terms $\text{Pgm} : \text{Exp}$ over the signature $\langle S, F \cup \text{Var} \rangle$, usually denoted simply by $\text{Pgm}$ if there is no danger of confusion, such that $\text{Exp}$ is a sort in $S^{\text{Pgm}}$. The arrows through which they are linked generalize the subterm relations; in this sense, a morphism $\langle \psi, \pi \rangle$ between programs $\text{Pgm}_1 : \text{Exp}_1$ and $\text{Pgm}_2 : \text{Exp}_2$ consists of

- a substitution $\psi : \text{var}(\text{Pgm}_1) \to \text{var}(\text{Pgm}_2)$, mapping the variables that occur in $\text{Pgm}_1$ to program expressions defined over the variables of $\text{Pgm}_2$, and
- a position $\pi$ in $\text{Pgm}_2$, that is a sequence of natural numbers that precisely identifies a particular occurrence of a subterm $\text{Pgm}_2 \upharpoonright \pi$ of $\text{Pgm}_2$,
such that $\psi^{tm}(pgm_1) = pgm_2 \upharpoonright \pi$. Their composition is defined componentwise, in a way that ensures the commutativity of the following diagram.

\[
\begin{array}{c}
pgm_1 : eXp_1 \\
\downarrow (\psi_1, \pi_1)
\end{array} \quad \begin{array}{c}
pgm_2 : eXp_2 \\
\downarrow (\psi_2, \pi_2)
\end{array} \quad \begin{array}{c}
pqm_3 : eXp_3 \\
\downarrow (\psi_1 \psi_2, \pi_1 \pi_2)
\end{array}
\]

**Specifications.** For each program expression $pgm : eXp$, a (program) specification is a triple of the form $\iota : [\rho, \rho']$, where $\iota$ is a position in $pgm$ indicating the ‘subprogram’ of $pgm$ whose behaviour is being analysed,\(^3\) and $\rho$ and $\rho'$ are pre- and post-conditions associated with $pgm \upharpoonright \iota$, formalized as (quantifier-free) POA-sentences over the signature $\langle S, F \cup \{st : State\} \rangle$. The intuitive interpretation is the usual one:

Whenever the program $pgm \upharpoonright \iota$ is executed in an initial state that satisfies the pre-condition $\rho$, and the execution terminates, the resulting final state satisfies the post-condition $\rho'$.

Note, however, that specifications cannot be evaluated over arbitrary program expressions because, due to the presence of program variables, some of the programs may not support a well-defined notion of execution. We will address this aspect in Section 5.2 by taking into account translations of specifications along morphisms whose codomains are ground program expressions. For now, it suffices to mention that the translation of a program specification $\iota : [\rho, \rho']$ of $pgm_1 : eXp_1$ along a morphism $\langle \psi, \pi \rangle : (pgm_1 : eXp_1) \rightarrow (pgm_2 : eXp_2)$ is defined as $(\pi \cdot \iota) : [\psi(\rho), \psi(\rho')]$ of $pgm_2 : eXp_2$.

**Ground orchestrations and properties.** As expected, ground program expressions are just expressions that do not contain variables: $(S, F)$-terms $pgm : eXp$ whose sort $eXp$ belongs to $S_{pgm}$. Consequently, they have a well-defined operational semantics, which means that we can check whether or not they meet the requirements of a given specification.

A specification $\iota : [\rho, \rho']$ is a property of a ground program $pgm : eXp$ if the following satisfaction condition holds for the preordered algebra $A$:

\[
A \vDash_{\text{POA}} \forall \{st, st' : State\} \cdot (\rho(st) \land (pgm \upharpoonright \iota, st) \rightarrow (st')) \Rightarrow \rho'(st').
\]

To keep the notation simple and, at the same time, to emphasize the roles of $st$ and $st'$, in the above POA-sentence, $\rho(st)$ is used just as another name for

\(^3\) The first component of specifications may be encountered in the literature [e.g. in Mor94] with a different meaning: the frame of the considered specification, that is the set of identifiers whose values may change during the execution of the program.
Formally, the sentences $\rho(\sigma) \land \rho'(\sigma')$ are obtained by translating $\rho$ and $\rho'$ along the $(\sigma, \tau)$-substitutions $[\sigma] \mapsto [\sigma, \sigma']$ given by $\sigma \mapsto \sigma$ and $\sigma \mapsto \sigma'$, respectively.

Asynchronous relational networks as developed in [FL13b] uphold a significantly different perspective on services: the emphasis is put not on the role of services in addressing design-time organisational aspects of complex, interconnected systems, but rather on their role in managing the run-time organisation.
interactions that are involved in such systems. In this section, we consider a
variant of the original theory of asynchronous relational networks that relies
on hypergraphs instead of graphs, and uses $\omega$-automata [Tho90; see also
PP04] instead of sets of traces as models of behaviour.

The notions discussed in this context depend upon elements of linear tem-
poral logic, and are introduced through syntactic structures that correspond
to specific temporal signatures and signature morphisms. However, the
proposed theory is largely independent of any logical framework of choice –
similarly to the way program expressions can be defined over a variety of
algebraic signatures – and can be easily adapted to any institution for which

1. the category of signatures is (finitely) cocomplete,
2. there exist cofree models along every signature morphism, meaning that the reduct
   functors determined by signature morphisms admit right adjoints,
3. the category of models of every signature has (finite) products, and
4. all model homomorphisms reflect the satisfaction of sentences.

In addition to the above requirements, we implicitly assume, as in many
other works on institutions [see e.g. Dia08; and also ST11, for more details],
that the considered logical system is closed under isomorphisms, meaning
that the satisfaction of sentences is invariant with respect to isomorphisms
of models. This property holds in most institutions; in particular, it holds in
the variant of temporal logic that we use here as a basis for the construction
of the orchestration scheme of asynchronous relational networks.

**Linear Temporal Logic.** In order to capture a more operational notion
of service orchestration, we work with an automata-based variant of the
institution $\mathsf{LTL}$ of linear temporal logic [PC96]. This logical system, denoted
$\mathsf{ALTL}$, has the same syntax as $\mathsf{LTL}$, which means that signatures are arbitrary
sets of actions, and that signature morphisms are just functions. With respect
to sentences, for any signature $A$, the set of $A$-sentences is defined as the
least set containing the actions in $A$ that is closed under standard Boolean
connectives and under the temporal operators $\text{next (}\bigcirc\text{)}$ and $\text{until (}\_\_\text{U}\_\_\text{)}$. As
usual, the derived temporal sentences $\text{eventually } \rho$ (written $\Diamond \rho$) and $\text{always}
\rho$ (written $\Box \rho$) stand for $\text{true } \_\text{U} \rho$ and $\neg (\text{true } \_\text{U} \neg \rho)$ respectively.

The semantics of $\mathsf{ALTL}$ is defined over (non-deterministic) Muller auto-
mata [Mul63] instead of the more conventional temporal models. This means
that, in the present setting, the models of a signature $A$ are Muller automata
$\Lambda = \langle Q, \mathcal{P}(A), \Delta, I, \mathcal{F} \rangle$, which consist, besides the (finite) set $Q$ of states, the
alphabet $\mathcal{P}(A)$, and the transition relation $\Delta \subseteq Q \times \mathcal{P}(A) \times Q$, of a subset $I \subseteq Q$ of initial states, and of a subset $\mathcal{F} \subseteq \mathcal{P}(Q)$ of (non-empty) final-state sets.

The satisfaction relation is still essentially based upon the satisfaction between traces and (linear) temporal sentences: an automaton $\Lambda$ satisfies a sentence $\rho$ if every trace accepted by $\Lambda$ satisfies $\rho$. To be more precise, let us first recall that a trace over $A$ is an (infinite) sequence $\lambda \in \mathcal{P}(A)^\omega$, and that a run of an automaton $\Lambda$ defined as above on a trace $\lambda$ is a state sequence $q \in Q^\omega$ such that $q(0) \in I$ and $(q(i), \lambda(i), q(i + 1)) \in \Delta$ for every $i \in \omega$. A run $q$ is said to be successful if its infinity set, $\text{Inf}(q)$, that is the set of states that occur infinitely often in $q$, is a member of $\mathcal{F}$. Then, a trace $\lambda$ is accepted by $\Lambda$ if there exists a successful run of $\Lambda$ on $\lambda$. Finally, given a trace $\lambda$ (that can be presumed to be accepted by $\Lambda$) and $i \in \omega$, we use the notation $\lambda(i..)$ to indicate the suffix of $\lambda$ that starts at $\lambda(i)$. The satisfaction of temporal sentences by traces can now be defined by structural induction, as follows:

$$
\lambda \vdash a \text{ if and only if } a \in \lambda(0), \\
\lambda \vdash \neg \rho \text{ if and only if } \lambda \not\vdash \rho, \\
\lambda \vdash \bigvee E \text{ if and only if } \lambda \vdash \rho \text{ for some } \rho \in E, \\
\lambda \vdash \bigcirc \rho \text{ if and only if } \lambda(1..) \vdash \rho, \text{ and } \\
\lambda \vdash \rho_1 \mathbin{\bigcirc} \rho_2 \text{ if and only if } \lambda(i..) \vdash \rho_2 \text{ for some } i \in \omega \\
\text{ and } \lambda(j..) \vdash \rho_1 \text{ for all } j < i,
$$

where $a$ is an action in $A$, $\rho, \rho_1, \rho_2$ are $A$-sentences, and $E$ is a finite set of $A$-sentences.

One can easily see that the first of the hypotheses 1–4 that form the basis of the present study of asynchronous relational networks is satisfied by $\mathcal{ALTL}$, as it corresponds to a well-known result about the existence of small colimits in Set. In order to check that the remaining three properties hold as well, let us first recall that a homomorphism $h: \Lambda_1 \rightarrow \Lambda_2$ between Muller automata $\Lambda_1 = \langle Q_1, \mathcal{P}(A), I_1, F_1 \rangle$ and $\Lambda_2 = \langle Q_2, \mathcal{P}(A), I_2, F_2 \rangle$ (over the same alphabet) is a function $h: Q_1 \rightarrow Q_2$ such that $(h(p), \alpha, h(q)) \in \Delta_2$ whenever $(p, \alpha, q) \in \Delta_1$, $h(I_1) \subseteq I_2$, and $h(F_1) \subseteq F_2$. We also note that for any map $\sigma: A \rightarrow A'$ (i.e. for any signature morphism) and any Muller automaton $\Lambda' = \langle Q', \mathcal{P}(A'), I', F' \rangle$, the reduct $\Lambda' |_{\sigma}$ is the automaton $\langle Q', \mathcal{P}(A), I', F' \rangle$ with the same states, initial states, and final-state sets as $\Lambda'$, and with the transition relation given by $\Delta' |_{\sigma} = \{(p', \sigma^{-1}(\alpha'), q') \mid (p', \alpha', q') \in \Delta'\}$.

The following results enable us to use the institution $\mathcal{ALTL}$ as a foundation for the subsequent development of asynchronous relational networks. In
particular, Proposition 5.1.4 ensures the existence of cofree Muller automata along signature morphisms; Proposition 5.1.5 allows us to form products of Muller automata based on a straightforward categorical interpretation of the fact that the sets of traces accepted by Muller automata, that is the regular \( \omega \)-languages, are closed under intersection [see e.g. Tho90]; and finally, Proposition 5.1.6 guarantees that all model homomorphisms reflect the satisfaction of temporal sentences.

**Proposition 5.1.4.** For every morphism of \( \operatorname{ALTL} \)-signatures \( \sigma : A \rightarrow A' \), the reduct functor \( \sigma : \operatorname{Mod}^{\operatorname{ALTL}}(A') \rightarrow \operatorname{Mod}^{\operatorname{ALTL}}(A) \) admits a right adjoint, which we denote by \( (\_)^\sigma \).

**Proof.** According to a general category-theoretic result concerning adjoint functors, it suffices to show that for any automaton \( \Lambda \) over the alphabet \( \mathcal{P}(A) \) there exists a universal arrow from \( \Lambda^\sigma \) to \( \Lambda \). Let us thus consider a Muller automaton \( \Lambda = \langle Q, \mathcal{P}(A), \Delta, I, \mathcal{F} \rangle \) over \( \mathcal{P}(A) \). We define the automaton \( \Lambda^\sigma = \langle Q, \mathcal{P}(A'), \Delta^\sigma, I, \mathcal{F} \rangle \) over the alphabet \( \mathcal{P}(A') \) by

\[
\Lambda^\sigma = \{(p, \alpha', q) \mid (p, \sigma^{-1}(\alpha'), q) \in \Delta\}.
\]

It is straightforward to verify that the identity map \( 1_Q \) defines a homomorphism of automata \( \Lambda^\sigma \rightarrow \Lambda \): for any transition \( (p, \alpha, q) \in \Delta^\sigma \), by the definition of the reduct functor \( \_^\sigma \), there exists a subset \( \alpha' \subseteq A' \) such that \( \sigma^{-1}(\alpha') = \alpha \) and \( (p, \alpha', q) \in \Delta^\sigma \); given the definition above of \( \Delta^\sigma \), it follows that \( (p, \sigma^{-1}(\alpha'), q) \in \Delta \), and hence \( (p, \alpha, q) \in \Delta \).

\[
\Lambda \xrightarrow{1_Q} \Lambda^\sigma \xrightarrow{\sigma} \Lambda^\sigma \quad \xrightarrow{\sigma} \Lambda^\sigma \xrightarrow{1_Q} \Lambda
\]

Let us now assume that \( h : \Lambda^\sigma \rightarrow \Lambda \) is another homomorphism of automata, with \( \Lambda' = \langle Q', \mathcal{P}(A'), \Delta', I', \mathcal{F}' \rangle \). Then, for any transition \( (p', \alpha', q') \in \Delta' \), by the definition of the functor \( \_^\sigma \), we have \( (p', \sigma^{-1}(\alpha'), q') \in \Delta^\sigma \). Since \( h \) is a homomorphism, \( (h(p'), \sigma^{-1}(\alpha'), h(q')) \in \Delta' \); this further implies, by the definition of \( \Delta^\sigma \), that \( (h(p'), \alpha', h(q')) \in \Delta^\sigma \). As a result, the map \( h \) is also a homomorphism of automata \( \Lambda' \rightarrow \Lambda^\sigma \). Even more, it is obviously the unique homomorphism \( \Lambda' \rightarrow \Lambda^\sigma \) (in the category of automata over \( \mathcal{P}(A') \)) such that \( h \circ 1_Q = h \) in the category of automata over \( \mathcal{P}(A) \).

**Proposition 5.1.5.** For any set of actions \( A \), the category \( \operatorname{Mod}^{\operatorname{ALTL}}(A) \) of Muller automata defined over the alphabet \( \mathcal{P}(A) \) admits (finite) products.
proof. Let \((\Lambda_i)_{i \in J}\) be a (finite) family of Muller automata over the alphabet \(\mathcal{P}(A)\), with \(\Lambda_i\) given by \((Q_i, \mathcal{P}(A), \Delta_i, I_i, \mathcal{T}_i)\) for every \(i \in J\). We define the automaton \(\Lambda = \langle Q, \mathcal{P}(A), \Delta, I, \mathcal{T} \rangle\) by

\[
Q = \prod_{i \in J} Q_i,
\]
\[
\Delta = \{(p, \alpha, q) \mid (p(i), \alpha, q(i)) \in \Delta_i \text{ for all } i \in J\},
\]
\[
I = \prod_{i \in J} I_i, \text{ and}
\]
\[
\mathcal{T} = \{S \subseteq Q \mid \pi_i(S) \in \mathcal{T}_i \text{ for all } i \in J\},
\]

where the functions \(\pi_i: Q \to Q_i\) are the corresponding projections of the Cartesian product \(\prod_{i \in J} Q_i\). By construction, it immediately follows that for every \(i \in J\), the map \(\pi_i\) defines a homomorphism of automata \(\Lambda \to \Lambda_i\). Even more, one can easily see that for any other family of homomorphisms \((h_i: \Lambda' \to \Lambda_i)_{i \in J}\), with \(\Lambda'\) given by \((Q', \mathcal{P}(A'), \Delta', I', \mathcal{T}')\), the unique map \(h: Q' \to Q\) such that \(h \circ \pi_i = h_i\), for all \(i \in J\), defines a homomorphism of automata as well. Therefore, the automaton \(\Lambda\), together with the projections \((\pi_i)_{i \in J}\), form the product of \((\Lambda_i)_{i \in J}\).

\[
\square
\]

**Proposition 5.1.6.** Let \(h: \Lambda_1 \to \Lambda_2\) be a homomorphism between automata \(\Lambda_1\) and \(\Lambda_2\) defined over an alphabet \(\mathcal{P}(A)\). Every temporal sentence over \(A\) that is satisfied by \(\Lambda_2\) is also satisfied by \(\Lambda_1\).

**Proof.** Suppose that the automaton \(\Lambda_i\) is given by \((Q_i, \mathcal{P}(A), \Delta_i, I_i, \mathcal{T}_i)\), for \(i \in \{1, 2\}\). Since the map \(h: Q_1 \to Q_2\) defines a homomorphism of automata, for every successful run \(\rho \in Q_1^\omega\) of \(\Lambda_1\) on a trace \(\lambda \in \mathcal{P}(A)^\omega\), the composition \(\rho \circ h\) yields a successful run of \(\Lambda_2\) on \(\lambda\). As a result, the automaton \(\Lambda_2\) accepts all the traces accepted by \(\Lambda_1\), which further implies that \(\Lambda_1\) satisfies all temporal sentences that are satisfied by \(\Lambda_2\).

\[
\square
\]

**Service components.** Following [FL13b], we regard service components as networks of processes that interact asynchronously by exchanging messages through communication channels. Messages are considered to be atomic units of communication. They can be grouped either into sets of messages that correspond to processes or channels, or into specific structures, called ports, through which processes and channels can be interconnected.

The ports can be viewed as sets of messages with attached polarities. As in [BZ83; BCT06] we distinguish between outgoing or published messages (labelled with a minus sign), and incoming or delivered messages (labelled with a plus sign).
**Definition 5.1.7** (Port). A port $M$ is a pair $\langle M^-, M^+ \rangle$ of disjoint (finite) sets of **published** and **delivered messages**. The set of all messages of $M$ is given by $M^- \cup M^+$ and is often denoted simply by $M$. Every port $M$ defines the set of actions $A_M$ as the union $A_{M^-} \cup A_{M^+}$, where

- $A_{M^-}$ is the set $\{ m! \mid m \in M^- \}$ of **publication actions** and
- $A_{M^+}$ is the set $\{ m! \mid m \in M^+ \}$ of **delivery actions**.

Processes are defined by sets of interaction points labelled with ports and by automata that describe their behaviour in terms of observable publication and delivery actions.

**Definition 5.1.8** (Process). A process $\langle X, (M_x)_{x \in X}, \Lambda \rangle$ consists of a (finite) set $X$ of **interaction points**, each point $x \in X$ being labelled with a port $M_x$, and a Muller automaton $\Lambda$ over $\mathcal{P}(A_M)$, where $M$ is the port given by

$$M^x = \bigcup_{x \in X} M_x^x = \{ x.m \mid x \in X, m \in M_x^x \}.$$ 

**Example 5.1.9.** In Figure 5.3, we depict a process named JP (for Journey Planner) that provides directions from a source to a target location. The process interacts with the environment by means of two ports, JP$_1$ and JP$_2$. The first of them is used to communicate with potential client applications; the request for directions (including the source and the target locations) is encoded into the incoming message `planJourney`, while the response is represented by the outgoing message `directions`. The second port defines messages that JP exchanges with other processes in order to complete its task; the outgoing message `getRoutes` can be seen as a query for all possible routes between the specified source and target locations, while the incoming messages `routes` and `timetables` define the result of the query and the timetables of the available transport services for the selected routes.

The behaviour of JP is given by the Muller automaton depicted in Figure 5.4, whose final-state sets contain $q_0$ whenever they contain $q_5$. We can describe it informally as follows: whenever the process JP receives a request `planJourney`, it immediately initiates the search for the available routes by sending the
message `getRoutes`; it then waits for the delivery of the routes and of the corresponding timetables (given here by the messages routes and timetables), and, once it receives both, it compiles the directions and replies to the client.

**Figure 5.4. The automaton \( \Lambda_{IP} \)**

**Remark 5.1.10.** To generalize *Definition 5.1.8* to an arbitrary institution (subject to the four technical assumptions listed at the beginning of the section), we first observe that every polarity-preserving map \( \theta \) between ports \( M \) and \( M' \) defines a function \( A_\theta : A_M \to A_{M'} \) – i.e. a morphism of \( \text{ALTL} \)-signatures – usually denoted simply by \( \theta \), that maps every publication action \( m! \) to \( \theta(m!) \) and every delivery action \( m¡ \) to \( \theta(m¡) \). Moreover, for any process \( \langle X, (M_x)_{x \in X}, \Lambda \rangle \), the injections \( (\iota_x : A_{M_x} \to A_{M})_{x \in X} \) define a coproduct in the category of \( \text{ALTL} \)-signatures. This allows us to introduce an abstract notion of process as a triple \( \langle X, (\Sigma_x : A_{M_x} \to \Sigma)_{x \in X}, \Lambda \rangle \) that consists of a set \( X \) of interaction points, each point \( x \in X \) being labelled with a port signature \( \Sigma_x \) (usually defining a coproduct), and a model \( \Lambda \) of \( \Sigma \).

Processes communicate by transmitting messages through channels. As in [BZ83; FL13b], channels are bidirectional: they may transmit both incoming and outgoing messages.

**Definition 5.1.11 (Channel).** A channel is a pair \( \langle M, \Lambda \rangle \) that consists of a (finite) set \( M \) of messages and a Muller automaton \( \Lambda \) over the alphabet \( \mathcal{P}(A_M) \), where \( A_M \) is given by the union \( A_M^- \cup A_M^+ \) of the sets of actions \( A_M^- = \{ m! | m \in M \} \) and \( A_M^+ = \{ m¡ | m \in M \} \).

Note that channels do not provide any information about the communicating entities. In order to enable given processes to exchange messages, channels need to be attached to their ports, thus forming connections.

---

\(^5\) In the graphical representation, transitions are labelled with propositional sentences, as in [AS87]; this means that there exists a transition for any propositional model (i.e. set of actions) of the considered sentence.
**Definition 5.1.12** (Connection). A connection \( \langle M, \Lambda, (\mu_x : M \rightarrow M_x)_{x \in X} \rangle \) between the ports \( M_x \), for \( x \in X \), consists of a channel \( \langle M, \Lambda \rangle \) and a (finite) family of partial attachment injections \( (\mu_x : M \rightarrow M_x)_{x \in X} \) such that the set \( M \) corresponds to the union \( \bigcup_{x \in X} \text{dom}(\mu_x) \) and, for any point \( x \in X \),

\[
\mu_x^{-1}(M_x) \subseteq \bigcup_{y \in X \setminus \{x\}} \mu_y^{-1}(M_y).
\]

This notion of connection generalizes the one found in [FL13b] so that messages can be transmitted between more than two ports. The additional condition ensures in this case that messages are well paired: every published message of \( M_x \), for \( x \in X \), is paired with a delivered message of \( M_y \), for \( y \in X \setminus \{x\} \), and vice versa. One can also see that for any binary connection the attachment injections have to be total functions; therefore, any binary connection is also a connection in the sense of [FL13b].

**Example 5.1.13.** To illustrate how the process JP can send or receive messages, we consider the connection \( C \) depicted in Figure 5.5, which moderates the flow of messages between the port JP2 and two other ports, R1 and R2.

![Figure 5.5. The Journey Planner’s connection](image)

The underlying channel of \( C \) is given by the set of messages \( M = \{g, r, t\} \) together with the automaton \( \Lambda_C \) that specifies the delivery of all published messages without any delay; \( \Lambda_C \) can be built as the product of the automata \( \Lambda_m \), for \( m \in M \), whose transition map is depicted in Figure 5.6, and whose sets of states are all marked as final.

![Figure 5.6. The automaton \( \Lambda_m \)](image)

The channel is attached to the ports JP2, R1, and R2 through the injections

- \( \mu_{JP2} : M \rightarrow M_{JP2} \) given by \( g \mapsto \text{getRoutes}, r \mapsto \text{routes} \) and \( t \mapsto \text{timetables} \),
• \( \mu_{R_1} : M \rightarrow M_{R_1} \) given by \( g \mapsto \text{getRoutes} \) and \( r \mapsto \text{routes} \), and

• \( \mu_{R_2} : M \rightarrow M_{R_2} \) given by \( r \mapsto \text{routes} \) and \( t \mapsto \text{timetables} \).

These injections specify the actual senders and receivers of messages. For instance, the message \( g \) is delivered only to the port \( R_1 \) (because \( \mu_{R_2} \) is not defined on \( g \)), whereas \( r \) is simultaneously delivered to both \( JP_2 \) and \( R_2 \).

As already suggested in Examples 5.1.9 and 5.1.13, processes and connections have dual roles, and they interpret the polarities of messages accordingly. In this sense, processes are responsible for publishing messages (i.e. they regard delivered messages as inputs and published messages as outputs), while connections are responsible for delivering messages.

This dual nature of connections can be made explicit by taking into account, for every connection \( \langle M, \Lambda, (\mu_x : M \rightarrow M_x)_{x \in X} \rangle \), partial translations \( (A_{\mu_x} : A_M \rightarrow A_{M_x})_{x \in X} \) of the actions defined by the channel into actions defined by the ports, as follows:

\[
\text{dom}(A_{\mu_x}) = \{m! \mid m \in \mu_x^{-1}(M^-_x)\} \cup \{m_! \mid m \in \mu_x^{-1}(M^+_x)\},
\]

\[
A_{\mu_x}(m!) = \mu_x(m)! \text{ for all messages } m \in \mu_x^{-1}(M^-_x),
\]

\[
A_{\mu_x}(m_!) = \mu_x(m)_! \text{ for all messages } m \in \mu_x^{-1}(M^+_x).
\]

When there is no danger of confusion, we may also designate the partial translations \( A_{\mu_x} : A_M \rightarrow A_{M_x} \) simply by \( \mu_x \).

**Remark 5.1.14.** Just as in the case of processes, we can define connections based on an arbitrary logical system, without relying on messages. To achieve this goal, note that every connection \( \langle M, \Lambda, (\mu_x : M \rightarrow M_x)_{x \in X} \rangle \) determines a family of spans of \( \mathcal{LTL} \)-signature morphisms

\[
A_M \xrightarrow{\mu_x} \text{dom}(\mu_x) \xrightarrow{\mu_x} A_{M_x}
\]

indexed by points \( x \in X \). This allows us to consider connections more generally as triples \( \langle \Sigma, \Lambda, (t_x : \Sigma'_x \rightarrow \Sigma, \mu_x : \Sigma'_x \rightarrow \Sigma_x)_{x \in X} \rangle \) in which the signature \( \Sigma \) and the model \( \Lambda \) of \( \Sigma \) abstract the channel component, while the spans \( (t_x, \mu_x)_{x \in X} \) capture the attachment of port signatures to the channel.

We can now define asynchronous networks of processes as hypergraphs having vertices labelled with ports and hyperedges labelled with processes or connections.

**Definition 5.1.15 (Hypergraph).** A hypergraph \( \langle X, E, \gamma \rangle \) consists of a set \( X \) of vertices or nodes, a set \( E \) of hyperedges, disjoint from \( X \), and an incidence map
$\gamma : E \to \mathcal{P}(X)$ defining, for every hyperedge $e \in E$, a non-empty set $\gamma_e \subseteq X$ of vertices it is incident with.

A hypergraph $\langle X, E, \gamma \rangle$ is said to be edge-bipartite if it admits a distinguished partition of $E$ into subsets $F$ and $G$ such that no adjacent hyperedges belong to the same part, meaning that for every two hyperedges $e_1, e_2 \in E$ such that $\gamma_{e_1} \cap \gamma_{e_2} \neq \emptyset$, either $e_1 \in F$ and $e_2 \in G$, or $e_1 \in G$ and $e_2 \in F$.

Hypergraphs have been used extensively in the context of graph-rewriting-based approaches to concurrency, including service-oriented computing [e.g. Fer+05; BGLL09]. We use them instead of graphs [see FL13b] because they offer a more flexible mathematical framework for handling the notions of variable and variable binding required in Section 5.2.

**Definition 5.1.16** (Asynchronous relational network – ARN). An asynchronous relational network $\mathfrak{M} = \langle X, P, C, \gamma, M, \mu, \Lambda \rangle$ consists of a (finite) edge-bipartite hypergraph $\langle X, P, C, \gamma \rangle$ of points $x \in X$, computation hyperedges $p \in P$ and communication hyperedges $c \in C$, together with

- a port $M_x$ for every point $x \in X$,
- a process $\langle \gamma_p, (M_x)_{x \in \gamma_p}, \Lambda_p \rangle$ for every hyperedge $p \in P$, and
- a connection $\langle M_c, \Lambda_c, (\mu^c : M_c \to M_x)_{x \in \gamma_c} \rangle$ for every hyperedge $c \in C$.

**Example 5.1.17.** By putting together the process and the connection presented in Examples 5.1.9 and 5.1.13, we obtain the ARN JourneyPlanner depicted in Figure 5.7. Its underlying hypergraph consists of the points $J P_1, J P_2, R_1$, and $R_2$, the computation hyperedge $J P$, the communication hyperedge $C$, and the incidence map $\gamma$ given by $\gamma_p = \{J P_1, J P_2\}$ and $\gamma_c = \{J P_2, R_1, R_2\}$.

**Figure 5.7.** The ARN JourneyPlanner

**The Orchestration Scheme of Asynchronous Relational Networks.**

Let us now focus on the manner in which ARNs can be organized to form an orchestration scheme. This provides a convenient mechanism for dealing with the added complexity of ARNs (of a different nature than the component abstraction considered in [FL13b]) that will prove to be particularly suited
for the present investigation of the logic-programming semantics of services. We begin with a brief discussion on the types of points of ARNS, which will enable us to introduce notions of morphism of ARNS and ground ARN.

An interaction point of an ARN \( \mathcal{N} \) is a point of \( \mathcal{N} \) that is not bound to both computation and communication hyperedges. We distinguish between two types of interaction points, called requires- and provides-points, as follows.

**Definition 5.1.18 (Requires- and provides-point).** A requires-point of an ARN \( \mathcal{N} \) is a point of \( \mathcal{N} \) that is incident only with a communication hyperedge. Similarly, a provides-point of \( \mathcal{N} \) is incident only with a computation hyperedge.

For the ARN JourneyPlanner depicted in Figure 5.7, the points \( R_1 \) and \( R_2 \) are requires-points (incident with the communication hyperedge C), whereas \( JP_1 \) is a provides-point (incident with the computation hyperedge JP).

**Orchestrations.** In order to describe ARNS as orchestrations we first need to equip them with appropriate notions of morphism and composition of morphisms. Morphisms of ARNS correspond to injective homomorphisms between their underlying hypergraphs, and are required to preserve all labels, except those associated with points that, like the requires-points, are not incident with computation hyperedges.

**Definition 5.1.19 (Homomorphism of hypergraphs).** A homomorphism \( h \) between hypergraphs \( (X_1, E_1, \gamma^1) \) and \( (X_2, E_2, \gamma^2) \) consists of a pair of functions \( h: X_1 \to X_2 \) and \( h: E_1 \to E_2 \) such that for any vertex \( x \in X_1 \) and hyperedge \( e \in E_1, x \in \gamma^1_e \) if and only if \( h(x) \in \gamma^2_{h(e)} \).

**Definition 5.1.20 (Morphism of ARNS).** A morphism \( \theta \) between ARNS \( \mathcal{N}_1 = (X_1, P_1, C_1, \gamma^1, M^1, \mu^1, \Lambda^1) \) and \( \mathcal{N}_2 = (X_2, P_2, C_2, \gamma^2, M^2, \mu^2, \Lambda^2) \) consists of

- an injective homomorphism \( \theta \) between the hypergraphs \( (X_1, P_1, C_1, \gamma^1) \) and \( (X_2, P_2, C_2, \gamma^2) \) such that \( \theta(P_1) \subseteq P_2 \) and \( \theta(C_1) \subseteq C_2 \), and
- a family \( \theta^{pt} \) of polarity-preserving injections \( \theta^{pt}_x: M^1_x \to M^2_{\theta(x)} \), for \( x \in X_1 \), such that

  - for every point \( x \in X_1 \) incident with a computation hyperedge, \( \theta^{pt}_x = 1_{M^1_x} \),
  - for every computation hyperedge \( p \in P_1 \), \( \Lambda^1_p = \Lambda^2_{\theta(p)} \), and

\(^6\) To simplify the notation, we denote both the translation of vertices and the translation of hyperedges simply by \( h \).
for every communication hyperedge \( c \in C_1 \), \( M^1_c = M^2_{\theta(c)} \), \( \Lambda^1_c = \Lambda^2_{\theta(c)} \) and the following diagram commutes, for every point \( x \in \gamma^1_c \).

\[
\begin{array}{c}
M^1_c = M^2_{\theta(c)} \quad \mu^1_c \quad M^1_x \\
\downarrow \quad \theta^x_{\mu^1_c} \\
\mu^2_{\theta(c)} \quad \Lambda^1_c \quad \Lambda^2_{\theta(c)} \\
\end{array}
\]

It is straightforward to verify that the morphisms of ARNs can be composed in terms of their components. Their composition is associative and has left and right identities given by morphisms that consist solely of set-theoretic identities. We obtain in this way the first result supporting the construction of an orchestration scheme of ARNs.

**Proposition 5.1.21.** The morphisms of ARNs form a category, denoted \( \mathbf{ARN} \). \( \square \)

**Specifications.** To define specifications over given ARNs, we label their points with linear temporal sentences, much in the way we used pre- and post-conditions as labels for positions in terms when defining specifications of program expressions.

**Definition 5.1.22** (Specification over an ARN). For any ARN \( \mathcal{M} \), the set \( \text{Spec}(\mathcal{M}) \) of \( \mathcal{M} \)-specifications is the set of pairs \( \langle x, \rho \rangle \), usually denoted \( \math@{x}\rho \), where \( x \) is a point of \( \mathcal{M} \) and \( \rho \) is an ALTL-sentence over \( A_{M_x} \), that is over the set of actions defined by the port that labels \( x \).

The translation of specifications along morphisms of ARNs presents no difficulties: for every morphism \( \theta: \mathcal{M} \to \mathcal{M}' \), the map \( \text{Spec}(\theta): \text{Spec}(\mathcal{M}) \to \text{Spec}(\mathcal{M}') \) is given by

\[
\text{Spec}(\theta)(\math@{x}\rho) = \math@{B(x)}\text{Sen}_{\text{ALTL}}(\theta^x_{\rho})(\rho)
\]

for each point \( x \) of \( \mathcal{M} \) and each ALTL-sentence \( \rho \) over the actions of \( x \). Furthermore, it can be easily seen that it inherits the functoriality of the translation of ALTL-sentences, thus giving rise to the needed functor \( \text{Spec}: \mathbf{ARN} \to \mathbf{Set} \).

**Ground Orchestrations.** Morphisms of ARNs can also be regarded as refinements, because they formalize the embedding of networks with an intuitively simpler behaviour into networks that are more complex. This is achieved essentially by mapping each of the requires-points of the source ARN to a potentially non-requires-point of the target ARN, a point which can be looked at as the ‘root’ of a particular subnetwork of the target ARN. To
explain this aspect in more detail we introduce the notions of dependency and \( \text{ARN} \) defined by a point.

**Definition 5.1.23** (Dependency). Let \( x \) and \( y \) be two points of a \( \text{ARN} \) \( \mathcal{N} \). The point \( x \) is said to be *dependent* on \( y \) if there exists a path from \( x \) to \( y \) that begins with a computation hyperedge, that is, if there exists an alternating sequence \( x e_1 x_1 \ldots e_n y \) of (distinct) points and hyperedges of the underlying hypergraph \( (X, P, C, \gamma) \) of \( \mathcal{N} \) such that \( x \in \gamma e_1, y \in \gamma e_n, x_i \in \gamma e_i \cap \gamma e_{i+1}, \) for every \( 1 \leq i < n, \) and \( e_1 \in P. \)

**Definition 5.1.24** (Network defined by a point). For any \( \text{ARN} \) \( \mathcal{N} \) and any point \( x \) of \( \mathcal{N} \), the *network defined by \( x \) (relative to \( \mathcal{N} \))* is the full sub-\( \text{ARN} \) \( \mathcal{N}_x \) of \( \mathcal{N} \) determined by \( x \) and the points on which \( x \) is dependent.

One can now see that any morphism of \( \text{ARNs} \) \( \theta: \mathcal{N}_1 \to \mathcal{N}_2 \) assigns to each requires-point \( x \) of \( \mathcal{N}_1 \) the sub-\( \text{ARN} \) \( \mathcal{N}_{2, \theta(x)} \) of \( \mathcal{N}_2 \) defined by \( \theta(x) \).

**Example 5.1.25.** In Figure 5.8, we outline an extension of the network JourneyPlanner discussed in Example 5.1.17 that is obtained by attaching the processes \( \text{MS} \) (for Map Services) and \( \text{TS} \) (for Transport System) to the requires-points \( R_1 \) and \( R_2 \) of JourneyPlanner. Formally, the link between JourneyPlanner and the resulting \( \text{ARN} \) JourneyPlannerNet is given by a morphism \( \theta: \text{JourneyPlanner} \to \text{JourneyPlannerNet} \) that preserves all the labels, points and hyperedges of JourneyPlanner, with the exception of the requires-points \( R_1 \) and \( R_2 \), which are mapped to \( \text{MS}_1 \) and \( \text{TS}_1 \), respectively.

In this case, the point \( \text{MS}_1 \) only depends on itself, hence the sub-\( \text{ARN} \) of JourneyPlannerNet defined by \( \text{MS}_1 \), that is the \( \text{ARN} \) assigned to the requires-point \( R_1 \) of JourneyPlanner, is given by the process \( \text{MS} \) and its port, \( \text{MS}_1 \). In contrast, the point \( \text{JP}_1 \) depends on all the other points of JourneyPlannerNet, and thus it defines the entire \( \text{ARN} \) JourneyPlannerNet.

**Figure 5.8.** The \( \text{ARN} \) JourneyPlannerNet

In view of the above observation, we may consider the requires-points of asynchronous relational networks as counterparts of the (program) variables
used in program expressions, and their morphisms as substitutions. This leads us to the following definition of ground ARNs.

**Definition 5.1.26.** An ARN is said to be ground if it has no requires-points.

**Properties.** The evaluation of specifications with respect to ground ARNs relies on the concepts of diagram of a network and automaton (i.e. $\mathsf{ALTL}$-model) defined by a point, whose purpose is to describe the observable behaviour of a ground ARN through one of its points. We start by extending Remarks 5.1.10 and 5.1.14 from processes and connections to ARNs.

**Fact 5.1.27** (Diagram of an ARN). Every ARN $\mathcal{N} = \langle X, P, C, \gamma, M, \mu, \Lambda \rangle$ defines a diagram $D_{\mathcal{N}}: J_{\mathcal{N}} \to \mathsf{Sig}^{\mathsf{ALTL}}$ as follows:

- $J_{\mathcal{N}}$ is the free preordered category given by the set of objects

  \[
  X \cup P \cup C \cup \{ \langle c, x \rangle_{\mathcal{N}} \mid c \in C, x \in \gamma_c \}
  \]

  and the arrows

  - $\{ x \to p \mid p \in P, x \in \gamma_p \}$ for computation hyperedges, and
  - $\{ c \leftarrow \langle c, x \rangle_{\mathcal{N}} \to x \mid c \in C, x \in \gamma_c \}$ for communication hyperedges;

- $D_{\mathcal{N}}$ is the functor that provides the sets of actions of ports, processes and channels, together with the appropriate mappings between them. For example, given a communication hyperedge $c \in C$ and a point $x \in \gamma_c$,

  \[
  - D_{\mathcal{N}}(c) = A_{M_c}, \quad D_{\mathcal{N}}(\langle c, x \rangle_{\mathcal{N}}) = \text{dom}(\mu^c_x), \quad D_{\mathcal{N}}(x) = A_{M_x},
  \]

  - $D_{\mathcal{N}}(\langle c, x \rangle_{\mathcal{N}} \to c) = (\text{dom}(\mu^c_x) \subseteq A_{M_c})$, and

- $D_{\mathcal{N}}(\langle c, x \rangle_{\mathcal{N}} \to x) = \mu^c_x$.

We define the signature of an ARN by taking the colimit of its diagram, which is guaranteed to exist because $\mathsf{Sig}^{\mathsf{ALTL}}$ (i.e. Set) is finitely cocomplete.

**Definition 5.1.28** (Signature of an ARN). The signature of an ARN $\mathcal{N}$ is the colimiting cocone $\xi: D_{\mathcal{N}} \Rightarrow A_{\mathcal{N}}$ of the diagram $D_{\mathcal{N}}$.

The most important construction that allows us to define properties of ground ARNs is the one that defines the observed behaviour of a (ground) network at one of its points.

**Definition 5.1.29** (Automaton defined by a point). Let $x$ be a point of a ground ARN $\mathcal{G}$. The observed automaton $\Lambda_x$ at $x$ is the reduct $\Lambda_{\mathcal{G}_x} \uparrow \xi_x$, where

- $\mathcal{G}_x = \langle X, P, C, \gamma, M, \mu, \Lambda \rangle$ is the sub-ARN of $\mathcal{G}$ defined by $x$,

- $\xi: D_{\mathcal{G}_x} \Rightarrow A_{\mathcal{G}_x}$ is the signature of $\mathcal{G}_x$. 
• \( \Lambda_{\varnothing_x} \) is the product automaton \( \prod_{e \in P \cup C} \Lambda^e_x \), and

• \( \Lambda^e_x \) is the cofree expansion of \( \Lambda_e \) along \( \xi_e \), for any hyperedge \( e \in P \cup C \).

**Example 5.1.30.** Consider once again the (ground) ARN represented in Figure 5.8. The automaton defined by the point \( MS_1 \) is just \( \Lambda_{MS} \mid_{MS_1} \); this follows from the observation that the ARN defined by \( MS_1 \) consists exclusively of the process \( MS \) and the port \( MS_1 \). On the other hand, to obtain the automaton defined by the provides-point \( JP_1 \), one needs to compute the product of the cofree expansions of all four automata \( \Lambda_{JP} \), \( \Lambda_C \), \( \Lambda_{MS} \), and \( \Lambda_{TS} \). Based on Propositions 5.1.4 and 5.1.5, the resulting automaton has to accept precisely the projections to \( A_{MS_1} \) of those traces accepted by \( \Lambda_{JP} \) that are compatible with traces accepted by \( \Lambda_C \), \( \Lambda_{MS} \), and \( \Lambda_{TS} \), in the sense that together they give rise, by amalgamation, to traces over the alphabet of the network.

We now have all the necessary concepts for defining properties of ARNS.

**Definition 5.1.31** (Property of an ARN). Let \( \otimes_x \rho \) be a specification over a ground ARN \( \mathcal{G} \). Then \( \otimes_x \rho \) is a property of \( \mathcal{G} \) if and only if the automaton \( \Lambda_x \) observed at the point \( x \) in \( \mathcal{G} \) satisfies (according to the definition of satisfaction in \( A_{\text{LTL}} \)) the temporal sentence \( \rho \).

\[ \Lambda_x \models_{A_{\text{LTL}}} \rho \]

**Remark 5.1.32.** It is important to notice that not only the signature of an ARN, but also the various cofree expansions and products considered in Definition 5.1.29 are unique only up to an isomorphism. Consequently, the automaton defined by a point of a ground ARN is also unique only up to an isomorphism, which means that the closure of \( A_{\text{LTL}} \) under isomorphisms plays a crucial role in ensuring that the evaluation of specifications with respect to ground ARNS is well defined.

All we need now in order to complete the construction of the orchestration scheme of asynchronous relational networks is to show that the morphisms of ground ARNS preserve properties. This result depends upon the last of the four hypotheses we introduced at the beginning of the section: the reflection of the satisfaction of sentences by the model homomorphisms of the institution used as foundation for the construction of ARNS.

**Proposition 5.1.33.** For every morphism of ground ARNS \( \theta: \mathcal{G}_1 \to \mathcal{G}_2 \) and every property \( \otimes_x \rho \) of \( \mathcal{G}_1 \), the specification \( \text{Spec}(\theta)(\otimes_x \rho) \) is a property of \( \mathcal{G}_2 \).

**Proof.** Let \( \mathcal{G}^x_1 \) and \( \mathcal{G}^x_2 \) be the sub-ARNs of \( \mathcal{G}_1 \) and \( \mathcal{G}_2 \) determined by \( x \) and \( \theta(x) \) respectively, and let us also assume that \( \mathcal{G}^x_i = (X_i, P_i, C_i, \gamma^i, M^i, \mu^i, \Lambda^i) \)
and that \( \xi^i : D_{\Theta}^i \Rightarrow A_{\Theta}^i \) is the signature of \( \Theta^i \), for \( i \in \{1, 2\} \). Since \( \Theta_{\Theta} \rho \) is a property of \( \Theta_1 \), we know that the automaton \( \Lambda^1 \) observed at \( x \) in \( \Theta_1 \) satisfies \( \rho \). We also know that \( \Theta : \Theta_1 \rightarrow \Theta_2 \) defines the \( \text{ALTL} \)-signature morphism \( \Theta^2_{\Theta} : A_{M_2,0}\{i\} \rightarrow A_{M_2,0}\{i\} \) as the identity of \( A_{M_2,0}\{i\} \) (because \( \Theta_1 \) is ground); hence, the automaton \( \Lambda^2 \) observed at \( \Theta(x) \) in \( \Theta_2 \) is also a model of \( A_{M_2,0}\{i\} \).

By Proposition 5.1.6, \( \text{ALTL} \)-model homomorphisms reflect the satisfaction of sentences; therefore, in order to prove that \( \Lambda^2 \) satisfies \( \rho \) – and in this way, that \( \text{Spec}(\Theta)(\Theta_{\Theta}) \) is a property of \( \Theta_2 \) – it suffices to determine the existence of a homomorphism \( \Lambda^2_{\Theta(x)} \rightarrow \Lambda^1 \). To this end, recall that the automata \( \Lambda^1 \) and \( \Lambda^2 \) correspond to the reducts \( \Lambda^{\Theta^2} \uparrow_{\Theta^1} \) and \( \Lambda^{\Theta^2} \uparrow_{\Theta^2} \), where, for \( i \in \{1, 2\} \),

- \( \Lambda^{\Theta^2} \) is the product \( \prod_{e \in P_1 \cup C_i} \Lambda^{\Theta^2} \), equipped with projections \( \pi^i_{\Theta^2} : \Lambda^{\Theta^2} \rightarrow \Lambda^{\Theta^2} \),
- \( \Lambda^{\Theta^2} \), for \( e \in P_1 \cup C_i \), is the cofree expansion of \( \Lambda^i \) along \( \xi^i \), for which we denote the universal morphism from \( \uparrow_{\xi^i} \) to \( \Lambda^i \) by \( \epsilon^i : \Lambda^{\Theta^2} \uparrow_{\Theta^2} \), for which we denote the universal morphism from \( \uparrow_{\xi^i} \) to \( \Lambda^i \).

According to the description of the \textsc{arns} defined by given points, we can restrict \( \Theta \) to a morphism of \textsc{arns} from \( \Theta_1 \) to \( \Theta_2 \). Since \( \Theta_1 \) is ground, we further obtain, based on this restriction, a functor \( F : \mathcal{J}_{\Theta_1} \rightarrow \mathcal{J}_{\Theta_2} \) that makes the following diagram commutative.

\[
\begin{array}{ccc}
\mathcal{J}_{\Theta_1} & \xrightarrow{D_{\Theta}^2} & \mathcal{J}_{\Theta_2} \\
F \downarrow & & \downarrow \text{Sig}^{\text{ALTL}} \\
\mathcal{J}_{\Theta_1} & \xrightarrow{D_{\Theta}^2} & \mathcal{J}_{\Theta_2}
\end{array}
\]

This allows us to define the derived cocone \( F \cdot \xi^2 : D_{\Theta}^2 \Rightarrow A_{\Theta}^2 \), whose components are given, for example, by \( (F \cdot \xi^2)_x = \xi^2_{\Theta(x)} \). Since \( \xi^1 \) is the colimit of \( D_{\Theta}^1 \) it follows that there exists a (unique) morphism of cocones \( \sigma : \xi^1 \rightarrow F \cdot \xi^2 \), that is an \( \text{ALTL} \)-signature morphism \( \sigma : \Lambda_{\Theta}^1 \rightarrow \Lambda_{\Theta}^2 \) that satisfies, in particular, \( \xi^1_{\Theta(e)} \uparrow_{\Theta(e)} \sigma = \xi^2_{\Theta(e)} \) for every hyperedge \( e \in P_1 \cup C_1 \).

We obtain in this way, for every hyperedge \( e \in P_1 \cup C_1 \), the composite morphism \( \pi^2_{\Theta(e)} \uparrow_{\Theta(e)} \xi^2_{\Theta(e)} \Rightarrow \Lambda_{\Theta}^2 \uparrow_{\Theta(e)} \) from \( \Lambda_{\Theta}^2 \uparrow_{\Theta(e)} \xi^2_{\Theta(e)} = \Lambda_{\Theta}^2 \uparrow_{\Theta(e)} \) to \( \Lambda^1_{\Theta(e)} = \Lambda^2_{\Theta(e)} \).

\[
\begin{array}{ccc}
\Lambda^1_{\Theta(e)} & \xrightarrow{\xi^1_{\Theta(e)}} & \Lambda^2_{\Theta(e)} \uparrow_{\Theta(e)} \\
D^1_{\Theta(e)} \downarrow & & \downarrow h_{\Theta(e)} \\
\Lambda^2_{\Theta(e)} \uparrow_{\Theta(e)} & \xrightarrow{\pi^2_{\Theta(e)} \downarrow_{\Theta(e)}} & \Lambda_{\Theta}^2 \uparrow_{\Theta(e)} = \Lambda_{\Theta}^2 \uparrow_{\Theta(e)} \uparrow_{\Theta(e)} \Lambda_{\Theta}^2 \uparrow_{\Theta(e)}
\end{array}
\]

Given that \( \Lambda_{\Theta}^{\Theta^2} \) is the cofree expansion of \( \Lambda^1 \) along \( \xi^1 \), we deduce that there
exists a (unique) morphism \( h_e : \Lambda_{o_2} \uparrow_\sigma \rightarrow \Lambda_{o_1} \uparrow_1 \) such that the above diagram is commutative. This implies, by the universal property of \( \Lambda_{o_1} \), the existence of a (unique) morphism \( h : \Lambda_{o_2} \uparrow_\sigma \rightarrow \Lambda_{o_1} \uparrow_1 \) such that \( h \downarrow \pi_1^1 = h_e \) for \( e \in P_1 \cup C_1 \).

\[
\begin{array}{c}
\Lambda_{o_1}^1 \\
\downarrow h \\
\Lambda_{o_2} \uparrow_\sigma \end{array}
\]

\[
\begin{array}{c}
\Lambda_{o_1}^1 \\
\pi_1^1 \\
\Lambda_{o_2} \uparrow_\sigma \end{array}
\]

It follows that the reduct \( h \uparrow_{o_1} \) is a morphism from \( \Lambda_{o_1}^1 \uparrow_\sigma \uparrow_{o_1} \) to \( \Lambda_{o_1}^1 \uparrow_{o_1} \). Then, to complete the proof, we only need to notice that \( \Lambda_{o_2} \uparrow_\sigma \uparrow_{o_1} = \Lambda_{o_2} \uparrow_{o_1} \uparrow_{o_1} = \Lambda_{o_1}^2 \) and \( \Lambda_{o_1}^1 \uparrow_{o_1} = \Lambda_{o_1}^1 \).

\[\Box\]

5.2 A LOGICAL VIEW ON SERVICE DISCOVERY AND BINDING

Building on the results of Section 5.1, let us now investigate how the semantics of the service overlay can be characterized using fundamental computational aspects of logic-programming such as unification and resolution. Our approach is founded upon a simple and intuitive analogy between concepts of service-oriented computing like service module and client application [see e.g. FLB11], and concepts such as clause and query that are specific to the relational variant of logic programming. In order to clarify this analogy, we rely on the institutional framework that we put forward in Chapter 3 to address the model-theoretic foundations of logic programming.

For the purpose of this section, it suffices to consider definite clauses, that is clauses of the form \( \forall X \cdot C \leftarrow H \), where \( X \) is a signature of variables (of a given generalized substitution system), and \( C \) and \( H \) correspond to ‘atomic’ sentences and sets of ‘atomic’ sentences over \( X \) respectively. This enables us to make explicit – at the level of logic-programming frameworks – the layered construction of clauses and queries from the sentences of an arbitrary generalized substitution system (regarded as ‘atomic’) by adding the necessary implications and conjunctions similarly to the way in which we added quantifiers in Section 3.2.1; this type of extension of a given generalized substitution system follows the well-known institution-independent semantics of Boolean connectives introduced in [Tar86; see also Bar74]. On that account, we will rely on a slightly different (and simpler) logical foundation for conventional logic programming, based on the atomic fragment of first-order logic – whose generalized substitution system we denote by AFOL_1 – in-
stead of the quantifier-free fragment. Note that every single-sorted first-order signature \( \langle F, P \rangle \) determines a substitution system

\[
(AFOL_1^\sharp(\text{AFOL}_1^\sharp(F, P)) \rightarrow (AFOL_1^\sharp(F, P) / \text{Room})
\]

in which \( \text{Subst}(F, P) \) is simply the category whose objects are sets of variables defined over \( \langle F, P \rangle \), and whose arrows are first-order substitutions (see Section 3.1.1). The room \( \text{AFOL}_1^\sharp(F, P) \) accounts for the (ground) atomic sentences given by \( \langle F, P \rangle \), the models of \( \langle F, P \rangle \), as well as the standard satisfaction relation between them. Finally, the functor \( (AFOL_1^\sharp(\text{AFOL}_1^\sharp(F, P)) \) maps every signature (i.e. every set) of variables \( X \) to the corridor \( \langle \alpha_{(F, P), X}, \beta_{(F, P), X} \rangle \),

\[
\begin{align*}
\alpha_{(F, P), X} & : \langle \text{Sen}(F, P), \text{Mod}(F, P), \vdash_{(F, P)} \rangle \rightarrow \langle \text{Sen}(F \cup X, P), \text{Mod}(F \cup X, P), \vdash_{(F \cup X, P)} \rangle \\
\beta_{(F, P), X} & : \langle \text{Sen}(F, P), \text{Mod}(F, P), \vdash_{(F, P)} \rangle \rightarrow \langle \text{Sen}(F \cup X, P), \text{Mod}(F \cup X, P), \vdash_{(F \cup X, P)} \rangle
\end{align*}
\]

where \( \alpha_{(F, P), X} \) and \( \beta_{(F, P), X} \) are the translation of sentences and the reduction of models that correspond to the inclusion of signatures \( \langle F, P \rangle \subseteq \langle F \cup X, P \rangle \).

5.2.1 A GENERALIZED SUBSTITUTION SYSTEM OF ORCHESTRATION SCHEMES

What is essential about orchestration schemes with respect to the development of the service-oriented variant of logic programming is that they can be organized as a category \( \text{OS} \) from which there exists a functor \( \text{OrcScheme} \) into \( \text{SubstSys} \) that allows us to capture some of the most basic aspects of service-oriented computing by means of logic-programming constructs. More precisely, orchestration schemes form the signatures of a generalized substitution system

\[
\text{OrcScheme}: \text{OS} \rightarrow \text{SubstSys}
\]

through which the notions of service module, application, discovery, and binding emerge as particular instances of the abstract notions of clause, query, unification, and resolution. In this sense, \( \text{OrcScheme} \) and \( \text{AFOL}_1^\sharp \) can be regarded as structures having the same role in the description of service-oriented and relational logic programming, respectively.

Morphisms of orchestration schemes are, intuitively, a way of encoding orchestrations. In order to understand how they arise in practice, let us
Consider a morphism $\varphi$ between two algebraic signatures $\Sigma$ and $\Sigma'$ used in defining program expressions. For instance, we may assume $\Sigma$ to be the signature of structured programs discussed in Example 5.1.2, and $\varphi : \Sigma \to \Sigma'$ its extension with a new operation symbol $\text{repeat\_until\_} : \text{Pgm\Cond} \to \text{Pgm}$. Then, it is easy to notice that the $\varphi$-translation of $\Sigma$-terms (defined over a given set of program variables) generalizes to a functor $F$ between the categories of program expressions defined over $\Sigma$ and $\Sigma'$. Moreover, the choice of $\varphi$ enables us to define a second functor $U$, from program expressions over $\Sigma'$ to program expression over $\Sigma$, based on the derived signature morphism [see e.g. ST11] $\Sigma' \to \Sigma$ that encodes the $\text{repeat\_until\_}$ operation as the term $1 \; \text{while not} \; 2 \; \text{do} \; 1 \; \text{done}$.

The functor $U$ is clearly a right inverse of $F$ with respect to ground program expressions, whereas in general, for every program expression $pgm$ over $\Sigma$ we actually obtain a morphism $\eta_{pgm} : pgm \to U(F(pgm))$ as a result of the potential renaming of program variables; thus, the morphism $\eta_{pgm}$ accounts for the translation of the program variables of $pgm$ along $F \circ U$. Furthermore, for every program expression $pgm'$ over $\Sigma'$, the translation of $\Sigma$-sentences determined by $\varphi$ extends to a map between the specifications over $U(pgm')$ and the specifications over $pgm'$, which, as we will see, can be used to define a translation of the specifications over a program expression $pgm$ (given by the signature $\Sigma$) to specifications over $F(pgm)$. With respect to the semantics, it is natural to expect that every program expression $pgm$ over $\Sigma$ has the same behaviour as $F(pgm)$ and, even more, that every program expression $pgm'$ over $\Sigma'$ (that may be built using $\text{repeat\_until\_}$), behaves in the same way as $U(pgm')$. These observations lead us to the following formalization of the notion of morphism of orchestration schemes.

**Definition 5.2.1** (Morphism of orchestration schemes). A *morphism* between orchestration schemes $(\text{Orc, Spec, Grc, Prop})$ and $(\text{Orc', Spec', Grc', Prop'})$ is a tuple $(F, U, \eta, \sigma)$, where

\[
\begin{array}{c}
\xymatrix{
\text{Orc} \ar[r]^{F} & \text{Orc'} \\
\xymatrix{
\ar@/_1pc/[rr]_{U} & 
}
\end{array}
\]

- $F$ and $U$ are functors as above such that $F(\text{Grc}) \subseteq \text{Grc'}$ and $U(\text{Grc'}) \subseteq \text{Grc}$,
- $\eta$ is a natural transformation $1_{\text{Orc}} \Rightarrow F \circ U$ such that $\eta_{g} = 1_{g}$ for $g \in |\text{Grc}|$,
- $\sigma$ is a natural transformation $U \circ \text{Spec} \Rightarrow \text{Spec'}$ such that for every ground

---

8 In this context, $1 : \text{Pgm}$ and $2 : \text{Cond}$ are variables that correspond to the arguments of the derived operation $1 \; \text{while not} \; 2 \; \text{do} \; 1 \; \text{done}$.
orchestration $g' \in |Grc'|$ and specification $\rho \in \text{Spec}(U(g'))$,
\[ \sigma_{g'}(\rho) \in \text{Prop'}(g') \quad \text{if and only if} \quad \rho \in \text{Prop}(U(g')). \]

**Example 5.2.2.** Let $\langle \Upsilon, \alpha, \beta \rangle$ be a morphism [see GB92; GR02] between two institutions $\mathcal{I}' = \langle \text{Sig}', \text{Sen}', \text{Mod}', \nu' \rangle$ and $\mathcal{I} = \langle \text{Sig}, \text{Sen}, \text{Mod}, \nu \rangle$ that are suitable for defining orchestration schemes of ARNS (according to the hypotheses introduced in Section 5.1.2). If (a) the signature functor $\Upsilon: \text{Sig}' \to \text{Sig}$ is cocontinuous, (b) the natural transformation $\beta: \text{Mod}' \Rightarrow \Upsilon^\text{op} \cdot \text{Mod}$ preserves cofree expansions and products, and, moreover, if (c) both $\Upsilon$ and $\beta$ admit sections, in the sense that there exist a functor $\Phi: \text{Sig} \to \text{Sig}'$ such that $\Phi \circ \Upsilon = 1_{\text{Sig}}$ and a natural transformation $\tau: \text{Mod} \Rightarrow \Phi^\text{op} \cdot \text{Mod}'$ such that $\tau \circ (\Phi^\text{op} \cdot \beta) = 1_{\text{Mod}}$, then $\langle \Upsilon, \alpha, \beta \rangle$ gives rise to a morphism $\langle F, U, \eta, \sigma \rangle$ between the orchestration schemes of ARNS defined over $\mathcal{I}$ and $\mathcal{I}'$.

In particular, the functor $F$ maps the diagram and the models that label an ARN defined over $\mathcal{I}$ to their images under $\Phi$ and $\tau$; similarly, $U$ maps ARNS defined over $\mathcal{I}'$ according to $\Upsilon$ and $\beta$; the natural transformation $\eta$ is just an identity, and $\sigma$ extends the $\alpha$-translation of sentences to specifications. The additional properties of $\Upsilon$ and $\beta$ are essential for ensuring that the observable behaviour of ground networks is preserved.

One may consider, for instance, the extension of $\text{ALTL}$ (in the role of $\mathcal{I}$) with new temporal modalities such as previous and since, as in [Kna+10]; this naturally leads to a morphism of orchestration schemes for which both $\Upsilon$ and $\beta$ would be identities. Alternatively, one may explore the correspondence between deterministic weak $\omega$-automata – which form a subclass of Muller automata – and sets of traces that are both B"uchi and co-B"uchi deterministically recognizable – for which a minimal automaton can be shown to exist [see e.g. MS97; L"od01]. In this case, in the roles of $\mathcal{I}$ and $\mathcal{I}'$ we could consider variants of $\text{ALTL}$ with models given by sets of traces and deterministic weak automata, respectively; $\Upsilon$ and $\alpha$ would be identities, $\beta$ would define the language recognized by a given automaton, and $\tau$ would capture the construction of minimal automata.

It is easy to see that the morphisms of orchestration schemes compose in a natural way in terms of their components, thus giving rise to a category of orchestration schemes.

---

9. Note that, to ensure that model reducts are well defined for deterministic automata, one may need to restrict signature morphisms to injective maps.
PROPOSITION 5.2.3. Orchestration-scheme morphisms can be composed as follows:

\[
(F, U, \eta, \sigma) \circ (F', U', \eta', \sigma') = (F \, \circ \, F', U' \, \circ \, U, \eta' \, \circ \, \eta, (U' \, \circ \, \sigma) \, \circ \, \sigma').
\]

Under this composition, morphisms of orchestration schemes form a category \( \mathcal{OS} \).

The definition of the functor \( \text{OrcScheme} \) is grounded on two simple ideas:

1. Orchestations can be regarded as signatures of variables; they provide sentences in the form of specifications, and models as morphisms into ground orchestrations – which can also be seen, in the case of ARNS, for example, as collections of ground networks assigned to the ‘variables’ of the considered orchestration. In addition, we can define a satisfaction relation between the models and the sentences of an orchestration based of the evaluation of specifications with respect to ground orchestrations. In this way, every orchestration scheme yields an institution whose composition resembles that of the so-called institutions of extended models [see SML04].

2. There is a one-to-one correspondence between institutions and substitution systems defined over the initial room \( \langle \emptyset, 1, \emptyset \rangle \) – the room given by the empty set of sentences, the terminal category \( 1 \), and the empty satisfaction relation. The effect of this is that a clause can be described as ‘correct’ whenever it is satisfied by the sole model of \( \langle \emptyset, 1, \emptyset \rangle \); therefore, we obtain precisely the notion of correctness of a service module [FLB11]: all models of the underlying signature of variables, that is of the orchestration, that satisfy the antecedent of the clause satisfy its consequent as well.

Formally, the generalized substitution system \( \text{OrcScheme} \) results from the composition of two functors, \( \text{Ins} : \mathcal{OS} \to \text{coIns} \) and \( \text{SS} : \text{coIns} \to \text{SubstSys} \), that implement the general constructions outlined above.

\[
\begin{align*}
\text{OrcScheme} & \xrightarrow{\text{Ins}} \text{coIns} \xrightarrow{\text{SS}} \text{SubstSys} \\
\mathcal{OS} & \longrightarrow \text{coIns} \longrightarrow \text{SubstSys}
\end{align*}
\]

The functor \( \text{Ins} \) carries most of the complexity of \( \text{OrcScheme} \), and is discussed in detail in Theorem 5.2.4. Concerning \( \text{SS} \), we recall from Section 2.3 that the category \( \text{coIns} \) of institution comorphisms can also be described as the category \( \, \longrightarrow \text{Room} \) of functors into \( \text{Room} \), and that any functor \( G : \mathcal{K} \to \mathcal{K}' \) can be extended to a functor \( \, \longrightarrow \mathcal{K} \) that is given essentially by the right-composition with \( G \). In particular, the isomorphism \( \text{Room} \to \langle \emptyset, 1, \emptyset \rangle / \text{Room} \) that maps every room \( \langle S, M, s \rangle \) to the unique cor-
For any orchestration scheme \( O = \langle \text{Orc}, \text{Spec}, \text{GrC}, \text{Prop} \rangle \), \( \text{Ins}(O) \) is the institution \( \langle \text{Orc}, \text{Spec}, \_ / \text{GrC}, \_ \rangle \) whose family of satisfaction relations is given by

\[
(\delta : o \to g) \vDash_o SP \quad \text{if and only if} \quad \text{Spec}(\delta)(SP) \in \text{Prop}(g)
\]

for every orchestration \( o \), every \( o \)-model \( \delta \) (i.e. every morphism of orchestrations \( \delta : o \to g \) such that \( g \) is ground), and every specification \( SP \) over \( o \);\(^{10}\)

- for any morphism of orchestration schemes \( \langle F, U, \eta, \sigma \rangle : O \to O', \) with \( O \) as above, and \( O' \) given by \( \langle \text{Orc}', \text{Spec}', \text{GrC}', \text{Prop}' \rangle \), \( \text{Ins}(F, U, \eta, \sigma) \) is the comorphism of institutions \( \langle F, \alpha, \beta \rangle : \text{Ins}(O) \to \text{Ins}(O') \) defined by

\[
\alpha_o = \text{Spec}(\eta_o) \downarrow \sigma_{F(o)} \quad \text{and} \quad \beta_o = \nu_{F(o)} \downarrow (\eta_o / \text{GrC})
\]

for every orchestration \( o \in |\text{Orc}| \), where \( \nu : \_ / \text{GrC}' \Rightarrow U^{\text{op}} \downarrow \_ / \text{GrC} \) is the natural transformation given by \( \nu_o(x) = U(x) \) for every orchestration \( o' \in |\text{Orc}'| \) and every object or arrow \( x \) of the comma category \( o' / \text{GrC}' \).

**Proof.** For the first part, all we need to show is that the satisfaction condition holds; but this follows easily since for every morphism of orchestrations \( \theta : o_1 \to o_2 \), every \( o_1 \)-specification \( SP \), and every \( o_2 \)-model \( \delta : o_2 \to g \),

\[
\delta \vDash_{o_2} \text{Spec}(\theta)(SP) \quad \text{if and only if} \quad \text{Spec}(\theta \downarrow \delta)(SP) \in \text{Prop}(g) \quad \text{if and only if} \quad (\theta / \text{GrC})(\delta) = \theta \downarrow \delta \vDash_{o_2} SP.
\]

As regards the second part of the statement, notice that \( \alpha \) and \( \beta \) are the natural transformations \( (\eta \cdot \text{Spec}) \downarrow (F \cdot \sigma) \) and \( (\eta^{\text{op}} \cdot \_ / \text{GrC}) \downarrow (F^{\text{op}} \cdot \nu) \), respectively. In order to verify that \( \langle F, \alpha, \beta \rangle \) is indeed a comorphism between \( \text{Ins}(O) \) and \( \text{Ins}(O') \), consider an orchestration \( o \) in \( \text{Orc} \), a model \( \delta' : F(o) \to g' \) of \( F(o) \), and a specification \( SP \) over \( o \). Assuming that \( \_ \) is the family of

---

\(^{10}\) Moreover, the institution \( \text{Ins}(O) \) is exact, because the functor \( \_ / \text{GrC} : \text{Orc}^{\text{op}} \to \text{Cat} \) is continuous (see e.g. [Mes80]).
satisfaction relations of \( \text{Ins}(O') \), we deduce that

\[
\delta' \vDash_{F'(\sigma)} \alpha_{\sigma}(SP)
\]

if \( \text{Spec}'(\delta')(\alpha_{\sigma}(SP)) \in \text{Prop}'(g') \)

by the definition of \( v'_{F'(\sigma)} \)

if \( \text{Spec}'(\delta')(\sigma_{F(\sigma)}(\text{Spec}(\eta_{\sigma}(SP)))) \in \text{Prop}'(g') \)

by the definition of \( \alpha_{\sigma} \)

if \( \sigma_{g'}(\text{Spec}(\eta_{\sigma} \circ U(\delta'))(SP)) \in \text{Prop}'(g') \)

by the naturality of \( \sigma \)

if \( \text{Spec}(\eta_{\sigma} \circ U(\delta'))(SP) \in \text{Prop}(U(g')) \)

since \( \text{Prop}(U(g')) = \sigma_{g'}^{-1}(\text{Prop}'(g')) \)

if \( \eta_{\sigma} \circ U(\delta') \vDash_{\sigma} SP \)

by the definition of \( v_{\sigma} \)

if \( \beta_{\sigma}(\delta') \vDash_{\sigma} SP \)

by the definition of \( \beta_{\sigma} \)

Finally, it is easy to see that \( \text{Ins} \) preserves identities. To prove that it also preserves composition, let \( \langle F, U, \eta, \sigma \rangle \) and \( \langle F', U', \eta', \sigma' \rangle \) be morphisms of orchestration schemes as below, and suppose that \( \text{Ins}(F, U, \eta, \sigma) = \langle F, \alpha, \beta \rangle \) and \( \text{Ins}(F', U', \eta', \sigma') = \langle F', \alpha', \beta' \rangle \).

\[
\begin{array}{ccc}
\langle F, U, \eta, \sigma, \rho \rangle & \xrightarrow{\langle \text{Orc}, \text{Spec}', \text{Grc}', \text{Prop}' \rangle} & \langle F', U', \rho', \alpha', \beta' \rangle \\
\langle \text{Orc}, \text{Spec}, \text{Grc}, \text{Prop} \rangle & \xrightarrow{\text{F} \circ F' U', U', \eta, \rho, \sigma, \sigma'} & \langle \text{Orc}'', \text{Spec}'', \text{Grc}'', \text{Prop}''' \rangle
\end{array}
\]

In addition, let \( v: (\_ / \text{Grc}') \Rightarrow U'^{\text{op}} \_ (\_ / \text{Grc}) \) and \( v': (\_ / \text{Grc}'') \Rightarrow U''^{\text{op}} \_ (\_ / \text{Grc}') \) be the natural transformations involved in the definitions of \( \beta \) and \( \beta' \), respectively. Based on the composition of morphisms of orchestration schemes and on the definition of \( \text{Ins} \), it follows that \( \text{Ins}((F, U, \eta, \sigma) \circ \langle F', U', \eta', \sigma' \rangle) \) is a comorphism of institutions of the form \( \langle F \circ F', \alpha'', \beta'' \rangle \), where \( \alpha'' \) and \( \beta'' \) are given by

\[
\alpha'' = \text{Spec}((\eta \circ (F \circ \eta' \circ U))_{\sigma}) \circ ((U' \circ \sigma) \circ \alpha'(F \circ F')_{\sigma})
\]

\[
\beta'' = (v' \circ (U'^{\text{op}} \circ v))_{(F \circ F')_{\sigma}} \circ ((\eta \circ (F \circ \eta' \circ U))_{\sigma} / \text{Grc}).
\]

In order to complete the proof, we need to show that \( \alpha'' = \alpha_{\sigma}(F \circ \alpha') \) and \( \beta'' = (F \circ \beta') \circ \beta \). Each of these equalities follows from a sequence of straightforward calculations that relies on the naturality of \( \sigma \) (in the case of \( \alpha'' \)), or on the naturality of \( v \) (in the case of \( \beta'' \)).

\[
\alpha'' = \text{Spec}(\eta_{\sigma}) \circ \text{Spec}(U(\eta'_{F(\sigma)})) \circ \sigma_{F \circ F'}(U')(\sigma) \circ \sigma'_{F \circ F'}(\sigma) = \alpha_{\sigma} \circ \alpha_{F(\sigma)}
\]

\[
= \text{Spec}(\eta_{\sigma}) \circ \sigma_{F(\sigma)} \circ \text{Spec}'(\eta'_{F(\sigma)}) \circ \sigma'_{F \circ F'}(\sigma) = \alpha_{\sigma} \circ \alpha'_{F(\sigma)}
\]

\[
= \text{Spec}(\eta_{\sigma}) \circ \sigma_{F(\sigma)} \circ \text{Spec}'(\eta'_{F(\sigma)}) \circ \sigma'_{F \circ F'}(\sigma) = \alpha_{\sigma} \circ \alpha'_{F(\sigma)}
\]
\[
\beta^\prime_o = v'_{(F;F')} (o) \triangleright (U(\eta_{F(o)}) \triangleright Grc) (\eta_o / Grc)
\]
\[
= v'_{(F;F')} (o) \triangleright (\eta'_{F(o)} / Grc') \triangleright v_{F(o)} (\eta_o / Grc) = \beta'_{F(o)} \triangleright \beta_o
\]

**Corollary 5.2.5.** Together with the category of orchestration schemes, the functor OrcScheme: OS → SubstSys defines a generalized substitution system.

We recall from Section 3.3 that, in order to be used as semantic frameworks for logic programming, generalized substitution systems need to ensure a weak model-amalgamation property between the models that are ground and those that are defined by signatures of variables. This property entails that the satisfaction of quantified sentences (and, in particular, of clauses and queries) is invariant under change of notation. In the case of OrcScheme, this means that the correctness property of service modules does not depend on the actual orchestration scheme over which the modules are defined.

**Proposition 5.2.6.** The generalized substitution system \(\langle OS, OrcScheme \rangle\) has weak model amalgamation.

**Proof.** Let \(\varphi\) be a morphism \(\langle F, U, \eta, o \rangle\) between orchestration schemes \(O\) and \(O'\) as in Definition 5.2.1, and let \(o\) be an orchestration of \(O\). Since orchestrations define substitution systems over the initial room \(\langle \emptyset, 1, \emptyset \rangle\), we can redraw the diagram of interest as follows:

![Diagram](image)

It is easy to see that the above diagram depicts a weak pullback if and only if \(\beta_{\varphi, o}\) is surjective on objects. By Theorem 5.2.4, we know that \(\beta_{\varphi, o}(\delta') = \eta_o \triangleright U(\delta')\) for every object \(\delta': F(o) \rightarrow g'\) of the comma category \(F(o) / Grc'\). Therefore, for every \(\delta: o \rightarrow g\) in \(|o / Grc|\) we obtain

\[
\beta_{\varphi, o}(F(\delta)) = \eta_o \triangleright U(F(\delta)) \quad \text{by Theorem 5.2.4}
\]
\[
= \delta \triangleright \eta_{\emptyset} \quad \text{by the naturality of} \ \eta
\]
\[
= \delta. \quad \text{because, by definition,} \ \eta_{\emptyset} \ \text{is an identity}
\]

**Remark 5.2.7.** In addition to model amalgamation, it is important to notice that, similarly to AFOL\(_1\), in OrcScheme the satisfaction of sentences is preserved by model homomorphisms. This is an immediate consequence of the
fact that, in every orchestration scheme, the morphisms of ground orchestra-
tions preserve properties: given an orchestration \( \sigma \), a specification \( SP \) over \( \sigma \),
and a homomorphism \( \zeta \) between \( \sigma \)-models \( \delta_1 \) and \( \delta_2 \) as depicted below, if
\( \text{Spec}(\delta_1)(SP) \) is a property of \( g_1 \) then \( \text{Spec}(\delta_2)(SP) = \text{Spec}(\zeta)(\text{Spec}(\delta_1)(SP)) \)
is a property of \( g_2 \); therefore, \( \delta_1 \models_{\text{OrcScheme}} SP \) implies \( \delta_2 \models_{\text{OrcScheme}} SP \).

\[
\begin{array}{c}
\delta_1 \\
\downarrow \zeta \\
\delta_2
\end{array}
\]

5.2.2 THE CLAUSAL STRUCTURE OF SERVICES

Given the above constructions, we can now consider a service-oriented no-
tion of clause, defined over the generalized substitution system OrcScheme
rather than AFOL\(^1\). Intuitively, this means that we replace first-order sig-
natures with orchestration schemes, sets of variables with orchestrations,
and first-order sentences (over given sets of variables) with specifications.
Furthermore, certain orchestration schemes allow us to identify structures
that correspond to finer-grained notions like variable and term: in the case
of program expressions, variables and terms have their usual meaning (al-
though we only take into account executable expressions), whereas in the
case of ARNs, variables and terms materialize as requires-points and sub-

\[
\text{Definition 5.2.8 (Service clause). A (definite) service-oriented clause over an}
\text{orchestration scheme } \mathcal{O} \text{ is a structure } \forall \sigma \cdot P \leftarrow R, \text{ also denoted}
\]

\[
P \leftarrow_{\sigma} R
\]

where \( \sigma \) is an orchestration of \( \mathcal{O} \), \( P \) is a specification over \( \sigma \) – called the
provides-interface of the clause – and \( R \) is a finite set of specifications over \( \sigma \) –
the requires-interface of the clause.

The semantics of service-oriented clauses is defined just as the semantics
of first-order clauses, except that they are evaluated within the generalized
substitution system OrcScheme instead of AFOL\(^1\). As mentioned before,
this means that we can only distinguish whether or not a clause is correct.

\[
\text{Definition 5.2.9 (Correct clause). A service-oriented clause } \forall \sigma \cdot P \leftarrow R \text{ is}
\text{said to be correct if for every morphism of orchestrations } \delta: \sigma \to g \text{ such that}
\]
g is a ground orchestration and $\text{Spec}(\delta)(R)$ consists only of properties of $g$, the specification $\text{Spec}(\delta)(P)$ is also a property of $g$.

In other words, a service-oriented clause is correct if its provides-interface is ensured by its orchestration and the specifications of its requires-interface.

**Example 5.2.10.** We have already encountered several instances of service clauses in the form of the program modules depicted in Figure 5.1. Their provides-interfaces and requires-interfaces are placed on the left-hand and right-hand side of their orchestrations, and are represented using symbolic forms that are traditionally associated with services.

To illustrate how service modules can be defined as clauses over ARNs, notice that the network JourneyPlanner introduced in Example 5.1.17 can orchestrate a module named Journey Planner that consistently delivers the requested directions, provided that the routes and the timetables can be obtained whenever they are needed. This can be described in logical terms through the following (correct) service-oriented clause:

\[
\begin{align*}
@R_1 \rho_1^p & \iff_{\text{JourneyPlanner}} \{ @R_1 \rho_1^p, @R_2 \rho_2^p \}
\end{align*}
\]

where $\rho_1^p$, $\rho_2^p$, and $\rho_2^p$ are the $\text{ALTL}$-sentences $\Box((\text{planJourney}_i \Rightarrow \Diamond \text{directions}_i))$, $\Box((\text{getRoutes}_i \Rightarrow \Diamond \text{routes}_i))$, and $\Box((\text{routes}_i \Rightarrow \Diamond \text{timetables}_i))$, respectively.

Client applications are captured in the present setting by service-oriented queries. They are defined similarly to service clauses, but their semantics is based on an existential quantification, not on a universal one.

**Definition 5.2.11** (Service query). A *service-oriented query* over an orchestration scheme $\mathcal{O}$ is a structure $\exists \phi \cdot Q$, also written

\[
\iff_{\phi} Q
\]

such that $\phi$ is an orchestration of $\mathcal{O}$, and $Q$ is a finite set of specifications over $\phi$ that defines the requires-interface of the query.

**Definition 5.2.12** (Satisfiable query). A service-oriented query $\exists \phi \cdot Q$ is *satisfiable* if there exists a morphism of orchestrations $\delta: \phi \rightarrow g$ such that $g$ is ground and all specifications in $\text{Spec}(\delta)(Q)$ are properties of $g$.

**Example 5.2.13.** In Figure 5.9, we outline the ARN of a possible client application for the service module Journey Planner discussed in Example 5.2.10. We specify the actual application, called Traveller, through the service query

\[
\iff_{\text{Traveller}} \{ @R_1 \rho_1^T \}
\]
given by the $\mathcal{ALTL}$-sentence $\Box(\text{getRoute} \Rightarrow \Diamond \text{route})$.

![Figure 5.9. The arn Traveller](image)

### 5.2.3 Resolution as Service Discovery and Binding

Let us now turn our attention to the dynamic aspects of service-oriented computing that result from the process of service discovery and binding [FLB21]. Service discovery represents, as in conventional logic programming, the search for a module (service clause) that can be bound to a given application (service query) in order to take it one step closer to a possible solution, that is to a ‘complete’ application capable of fulfilling its goal.

From a technical point of view, both discovery and binding are subject to matching the requires-interface of the application, or more precisely, one of its specifications, with the provides-interface of the module under consideration. This is usually achieved through a suitable notion of refinement of specifications. For instance, in the case of program expressions, given specifications $\iota_1: [\rho_1, \rho'_1]$ and $\iota_2: [\rho_2, \rho'_2]$ over programs $\text{pgm}_1: eXp_1$ and $\text{pgm}_2: eXp_2$, respectively, $\iota_2: [\rho_2, \rho'_2]$ refines $\iota_1: [\rho_1, \rho'_1]$ up to a cospan

$$\text{pgm}_1: eXp_1 \xrightarrow{\langle \psi_1, \pi_1 \rangle} \text{pgm}: eXp \xleftarrow{\langle \psi_2, \pi_2 \rangle} \text{pgm}_2: eXp_2$$

if by translation we obtain specifications that refer to the same position of $\text{pgm}: eXp$, that is $\pi_1 \cdot \iota_1 = \pi_2 \cdot \iota_2$, such that the pre-condition $\psi_2(\rho_2)$ is weaker than $\psi_1(\rho_1)$, and the post-condition $\psi_2(\rho'_2)$ is stronger than $\psi_1(\rho'_1)$:

$$\psi_1(\rho_1) \triangleright \text{POA} \psi_2(\rho_2) \quad \text{and} \quad \psi_2(\rho'_2) \triangleright \text{POA} \psi_1(\rho'_1).$$

This reflects the consequence rules introduced in [Hoa69] (see also [Mor94], whence we adopt the notation $\iota_1: [\rho_1, \rho'_1] \subseteq \iota_2: [\rho_2, \rho'_2]$ used in Figure 5.2).

In a similar manner, in the case of arns, a specification $@_{x_1} \rho_1$ over a network $\mathcal{N}_1$ is refined by another specification $@_{x_2} \rho_2$ over a network $\mathcal{N}_2$ up to a cospan of morphisms of arns $(\theta_1: \mathcal{N}_1 \rightarrow \mathcal{N}, \theta_2: \mathcal{N}_2 \rightarrow \mathcal{N})$ when $\theta_1(x_1) = \theta_2(x_2)$ and $\theta_{1,2}^{\text{POA}}(\rho_2) \triangleright \text{POA} \theta_{1,2}^{\text{ALTL}}(\rho_1)$ [see TF13]. Both of these notions of refinement generalize to the following concept of unification.
**Definition 5.2.14** (Service-oriented unification). Let $SP_1$ and $SP_2$ be specifications defined over orchestrations $o_1$ and $o_2$, respectively, of an arbitrary but fixed orchestration scheme. We say that the ordered pair $(SP_1, SP_2)$ is *unifiable* if there exists a cospan of morphisms of orchestrations as below,

$$
o_1 \xrightarrow{\theta_1} o \xleftarrow{\theta_2} o_2$$

called the *unifier* of $SP_1$ and $SP_2$, such that $\theta_2(SP_2) \equiv_{\text{OrcScheme}} \theta_1(SP_1)$.

Therefore, $(\theta_1, \theta_2)$ is a unifier of $SP_1$ and $SP_2$ if and only if, for every morphism of orchestrations $\delta: o \rightarrow g$ such that $g$ is a ground orchestration, if $\text{Spec}(\theta_2 \circ \delta)(SP_2)$ is a property of $g$ then so is $\text{Spec}(\theta_1 \circ \delta)(SP_1)$.

In conventional logic programming, the resolution inference rule simplifies the current goal and at the same time, through unification, yields computed substitutions that could eventually deliver a solution to the initial query. This process is accurately reflected in the case of service-oriented computing by *service binding*. Unlike relational logic programming, however, the emphasis is put not on the computed morphisms of orchestrations (i.e. on substitutions), but on the dynamic reconfiguration of the orchestrations (i.e. of the signatures of variables) that underlie the considered applications.

**Definition 5.2.15** (Service-oriented resolution). Let $\exists o_1 \cdot Q_1$ be a query and $\forall o_2 \cdot P_2 \leftarrow R_2$ a clause defined over an arbitrary but fixed orchestration scheme. A query $\exists o \cdot Q$ is said to be *derived by resolution* from $\exists o_1 \cdot Q_1$ and $\forall o_2 \cdot P_2 \leftarrow R_2$ using the *computed morphism* $\theta_1: o_1 \rightarrow o$ when

$$
\frac{\not\overbrace{\hfill o_1 \cdot Q_1 \hfill} \quad \overbrace{\not\overbrace{\overbrace{\hfill \theta_1(Q_1 \setminus \{SP_1\}) \cup \theta_2(R_2) \hfill}} \quad P_2 \leftarrow_{o_2} R_2}}{\quad \theta_1} \quad \theta_2}
$$

- $\theta_1$ can be extended to a unifier $(\theta_1, \theta_2)$ of a specification $SP_1 \in Q_1$ and $P_2$,
- $Q$ is the set of specifications given by the translation along $\theta_1$ and $\theta_2$ of the specifications in $Q_1 \setminus \{SP_1\}$ and $R_2$.

**Example 5.2.16.** Consider the service-oriented query and the service clause detailed in Examples 5.2.10 and 5.2.13. One can easily see that the single specification $\rho^T_1$ of the requires-interface of the application Traveller and the provides-interface $\rho^P_1$ of the module Journey Planner form a unifiable pair: they admit, for instance, the unifier $(\theta_1, \theta_2)$ given by

$$
\text{Traveller} \xrightarrow{\theta_1} \text{JourneyPlannerApp} \leftarrow_{\theta_2} \text{JourneyPlanner}
$$

• the **arn** `JourneyPlannerApp` depicted in **Figure 5.10**,
• the morphism \( \theta_1 \) that maps the point \( R_1 \) to \( JP_1 \), the communication hyperedge \( C \) to \( CJP \) and the messages `getRoute` and `route` of \( M_{R_1} \) to `planJourney` and directions, while preserving all the remaining elements of `Traveller`, and
• the inclusion \( \theta_2 \) of `JourneyPlanner` into `JourneyPlannerApp`.

![Diagram of service-oriented clause, query, and resolution](image)

**Figure 5.10. The arn `JourneyPlannerApp`**

It follows that we can derive by resolution a new service query given by the **arn** `JourneyPlannerApp` and the requires-specifications \( @R_1 p_1^{jp} \) and \( @R_2 p_2^{jp} \).

\[
\begin{align*}
\text{Traveller} & \quad \{ @R_1 p_1^{tp} \} \\
\text{journeyPlanner} & \quad \{ @R_1 p_1^{jp} , @R_2 p_2^{jp} \} \\
\end{align*}
\]

\[
\begin{align*}
\Rightarrow & \quad \text{journeyPlannerApp} \quad \{ @R_1 p_1^{jp} , @R_2 p_2^{jp} \} \\
\theta_1 & \quad \{ @R_1 p_1^{jp} , @R_2 p_2^{jp} \}
\end{align*}
\]

**The Logic-Programming Framework of Services.** The crucial property of the above notions of service-oriented clause, query, and resolution is that, together with the generalized substitution system OrcScheme used to define them, they give rise to a logic-programming framework. The construction is to a great extent self-evident, and it requires little additional consideration apart from the fact that, from a technical point of view, in order to define clauses and queries as quantified sentences, we need to extend OrcScheme by closing the sets of sentences that it defines under propositional connectives such as implication and conjunction. It should be noted, however, that the properties that guarantee the well-definedness of the resulting logic-programming framework such as the fact that its underlying generalized substitution system has weak model amalgamation (ensured by **Proposition 5.2.6**), and also the fact that the satisfaction of specifications is preserved by model homomorphisms (detailed in **Remark 5.2.7**), are far from trivial, especially when taking into account particular orchestration schemes (see e.g. **Proposition 5.1.33**).

By describing service discovery and binding as instances of unification and resolution (specific to the logic-programming framework of services)
we obtain not only a rigorously defined analogy between service-oriented computing and relational logic programming, but also a way to apply the general theory of logic programming developed in Section 3.3 to the particular case of services. For example, we gain a concept of solution to a service query that reflects the rather intuitive service-oriented notion of solution and, moreover, through Herbrand’s theorem, a characterization of satisfiable queries as queries that admit solutions.

**Definition 5.2.17** (Solution). A solution to a service-oriented query $\exists o \cdot Q$ consists of a morphism of orchestrations $\psi: o \rightarrow o'$ such that $o'$ has models, and every one of them satisfies the $\psi$-translations of the specifications in $Q$.

**Proposition 5.2.18.** A service query is satisfiable if and only if it has a solution.

Even more significant is the fact that logic programming provides us with a general search procedure that can be used to compute solutions to queries. The search is triggered by a query $\exists o \cdot Q$ and consists in the iterated application of resolution, that is of service discovery and binding, until the requires-interface of the derived service query consists solely of trivial specifications (tautologies); these are specifications whose translation along morphisms into ground orchestrations always gives rise to properties. Thus, whenever the search procedure successfully terminates we obtain a computed answer to the original query by sequentially composing the resulting computed morphisms. This is the process that led, for example, to the derivation of the program that calculates the quotient and the remainder obtained on dividing two natural numbers illustrated in Figure 5.2. The computed answer is given in this case by the sequence of substitutions

\[
\text{pgm} \mapsto \text{pgm}_1; \text{pgm}_2 \mapsto (\text{pgm}_3; \text{pgm}_4); \text{pgm}_2 \mapsto \cdots \\
\mapsto (q := 0; r := x); \text{while } y \leq r \text{ do} \\
\hspace{1cm} q := q + 1; r := r - y \\
\text{done.}
\]

In a similar manner, we can continue Example 5.2.16 towards the derivation of an answer to the Traveller application. To this purpose, we assume that Map Services and Transport System are two additional service modules that correspond to the processes $MS$ and $TS$ used in Example 5.1.25, and whose provides-interfaces meet the requires-specifications of the module Journey Planner. We obtain in this way the construction outlined in Figure 5.11.

The soundness of resolution, detailed in Proposition 5.2.19 below, entails
The derivation of an answer to the Traveller application

\[ \square (\text{getRoute} \Rightarrow \boxdot \text{route}) \]

\[ \square (\text{planJourney} \Rightarrow \boxdot \text{directions}) \]

\[ \square (\text{getRoutes} \Rightarrow \boxdot \text{routes}) \]

\[ \square (\text{getRoutes} \Rightarrow \boxdot \text{timetables}) \]
that the search for solutions is sound as well, in the sense that every computed answer to $\exists o \cdot Q$ is also a solution to $\exists o \cdot Q$. This fundamental result follows from Theorem 3.3.2.4 and ensures, in combination with Proposition 5.2.18, that the operational semantics of the service overlay given by discovery and binding is sound with respect to the notion of satisfiability of a service query.

**Proposition 5.2.19.** Let $\exists o \cdot Q$ be a service query derived by resolution from $\exists o_1 \cdot Q_1$ and $\forall o_2 \cdot P_2 \leftarrow R_2$ using the morphism $\theta_1 : o_1 \rightarrow o$. If $\forall o_2 \cdot P_2 \leftarrow R_2$ is correct then, for any solution $\psi$ to $\exists o \cdot Q$, $\theta_1; \psi$ is a solution to $\exists o_1 \cdot Q_1$. $\square$

The analogy between service-oriented computing and conventional logic programming that we have established in this chapter is presented in a condensed form in Table 5.1. To summarize, our approach to the logic-programming semantics of services is based on the identification of the binding of terms to variables in logic programming with the binding of orchestrations of services to those of software applications in service-oriented computing; the answer to a service query – the request for external services – is obtained through resolution using service clauses – orchestrated service interfaces – that are available from a repository. This departs from other works on the logic-programming semantics of service-oriented computing such as [KBG07] that actually considered implementations of the service discovery and binding mechanisms based on constraint logic programming.
Table 5.1: Correspondence between concepts of relational and service-oriented logic programming
SOLVING QUERIES OVER MODULAR LOGIC PROGRAMS

As in many other areas of computer science, in logic programming, modularization or structuring techniques are an essential element in managing the inherent complexity of large software systems—in this case, logic programs—at various stages of their development. This chapter is devoted to the study of modularization over the model-theoretic framework of abstract logic programming advanced in Section 3.3. More specifically, we investigate a series of properties related to the preservation and the reflection of both solutions and computed answers along morphisms of programs. We show that the preservation of solutions holds in general, thus ensuring that the general procedure for computing answers to queries is sound with respect to the modularization of logic programs, and identify a set of sufficient conditions under which the reflection property holds as well.

To start with, let us briefly examine how the specification-building operators of [ST88a]—which correspond to one of the most important general directions within the institution-independent studies of modularization—can be used in constructing modular logic programs. This leads to an alternative to the theory-oriented approach to structuring programs that we discussed in Example 3.3.6 in the context of relational logic programming. Both structuring mechanisms are particular instances of the general axiomatic approach proposed in Section 3.3, hence we can treat them uniformly by studying modularization over abstract logic-programming languages.

6.1 PROGRAM MODULES

In order to accommodate both the so-called loose semantics specific to relational logic programming and the free semantics necessary for specifying abstract data types, the equational logic programs presented in Section 4.1 are defined by means of modules like \texttt{NAT} and \texttt{ADD} that are built from finite presentations over \texttt{FOL}_{\leq} by iteration of \textit{structuring operators} such as union,
translation, and free semantics. Various other operators dedicated, for instance, to the derivation or the extension of modules (often parameterized by classes of signature morphisms or homomorphisms) have been considered in the specification literature [see Bor02; ST11; DT11]. To keep the presentation simple, we focus here only on the three aforementioned operators.

The equational logic-programming language $\mathcal{FOL}^\text{struc}$ defines programs as ‘terms’ formed from the programs of $\mathcal{FOL}^\text{pres}$ by repeated applications of the union, translation, and free-semantics operators listed below – together with the appropriate images of the resulting program modules under the functors $\text{Sign}$, $\text{Ax}$, and $\text{PMod}$. Similarly to the case of presentations, the morphisms of programs $\nu: P \rightarrow P'$ are morphisms of signatures $\nu: \text{Sign}(P) \rightarrow \text{Sign}(P')$ such that $M'\upharpoonright\nu \in \text{PMod}(P)$ for every model $M' \in \text{PMod}(P')$.

**Union.** For any two program modules $P_1$ and $P_2$ having the same signature $\Sigma$, the union $P_1 \cup P_2$ is also a program module, with

\[
\text{Sign}(P_1 \cup P_2) = \Sigma \\
\text{Ax}(P_1 \cup P_2) = \text{Ax}(P_1) \cup \text{Ax}(P_2) \\
\text{PMod}(P_1 \cup P_2) = \text{PMod}(P_1) \cap \text{PMod}(P_2).
\]

**Translation.** For any program module $P$ and any signature morphism $\varphi: \text{Sign}(P) \rightarrow \Sigma'$, translate $P$ by $\varphi$ is also a program module, with

\[
\text{Sign}($\text{translate } P \text{ by } \varphi$) = \Sigma' \\
\text{Ax}(\text{translate } P \text{ by } \varphi) = \varphi(\text{Ax}(P)) \\
\text{PMod}(\text{translate } P \text{ by } \varphi) = \text{Mod}(\varphi)^{-1}(\text{PMod}(P)).
\]

**Free semantics.** For any two program modules $P$ and $P'$, and any signature morphism $\varphi: \text{Sign}(P) \rightarrow \text{Sign}(P')$, free $P'$ over $P$ through $\varphi$ is also a program module, with

\[
\text{Sign}(\text{free } P' \text{ over } P \text{ through } \varphi) = \text{Sign}(P') \\
\text{Ax}(\text{free } P' \text{ over } P \text{ through } \varphi) = \text{Ax}(P') \\
\text{PMod}(\text{free } P' \text{ over } P \text{ through } \varphi) = \text{the full subcategory of } \text{PMod}(P') \text{ given by those } P'-\text{models that are free with respect to } \varphi \text{ over some } P-\text{model}.
\]

**Remark 6.1.1.** To describe the modules $\text{NAT}$ and $\text{ADD}$, note that, for any program module $P$, free $P$ is an abbreviation for free $P$ over $\emptyset$ through $\iota$, where
is the inclusion \( \emptyset \subseteq \text{Sign}(P) \), and that, for any other program module \( P' \) such that \( \text{Sign}(P) \) is a subsignature of \( \text{Sign}(P') \), \( P \) then \( P' \) is an abbreviation for \((\text{translate } P \text{ by } \iota) \cup P'\), where \( \iota \) is the inclusion \( \text{Sign}(P) \subseteq \text{Sign}(P') \).

### 6.2 FOUNDATIONS OF MODULAR LOGIC PROGRAMMING

Throughout this chapter, we will assume \( \mathcal{L} \) to be an arbitrary but fixed logic-programming language \( \langle \mathcal{L}P, \text{Sign}, \text{PMod}, \text{Ax} \rangle \) over a framework \( \mathcal{F} = \langle \mathcal{S}, \mathcal{C}, \mathcal{Q}, \# \rangle \).

Our first result concerns the preservation of queries and solutions (the denotational concept of answer to a query) along morphisms of programs.

**Proposition 6.2.1.** Let \( \exists X \cdot \rho \) be a query over a signature \( \Sigma \).

1. For every morphism of signatures \( \nu: \Sigma \to \Sigma' \), \( \nu(\exists X \cdot \rho) \) is a query over \( \Sigma' \).
2. For every morphism of programs \( \nu: \langle \Sigma, \Gamma \rangle \to \langle \Sigma', \Gamma' \rangle \) and every \( \langle \Sigma, \Gamma \rangle \)-solution \( \psi: X \to Y \) to \( \exists X \cdot \rho \), \( \nu(\psi)(\exists X \cdot \rho) \) is a \( \langle \Sigma', \Gamma' \rangle \)-solution to \( \nu(\exists X \cdot \rho) \).

**Proof.** For the first part, note that, by the definition of the translation of quantified sentences (see Section 3.2.1), \( \nu(\exists X \cdot \rho) = \exists \nu_X(X) \cdot \alpha_{\nu_X}(\rho) \). Since \( Q \) is a generalized subfunctor of LSen, it follows that \( \alpha_{\nu_X}(\rho) \in Q_{\Sigma'}(\nu_X(X)) \). Therefore, the quantified sentence \( \exists \nu_X(X) \cdot \alpha_{\nu_X}(\rho) \) is a \( \Sigma' \)-query.

For the second part, according to Definition 3.3.8, we need to check that \( \nu_X(Y) \) is conservative and that \( \langle \Sigma', \Gamma' \rangle \models_{\Sigma'} \forall \nu_X(Y) \cdot \nu(\psi)(\alpha_{\nu_X}(\rho)) \). Let us thus suppose that \( M' \) is a \( \Sigma' \)-model. Since \( Y \) is conservative (because \( \psi \) is a solution), there exists a \( Y \)-expansion \( N \) of \( M' \upharpoonright \nu \). It follows that \( M' \) and \( N \) are models of \( \Sigma' \) and \( Y \), respectively, such that \( M' \upharpoonright \nu = N \upharpoonright \Sigma \). This further implies, by the weak model-amalgamation property of \( \mathcal{S} \), that there exists a \( \nu_X(Y) \)-expansion \( N' \) of \( M' \) such that \( \beta_{\nu_Y}(N') = N \).

To prove that \( \langle \Sigma', \Gamma' \rangle \) entails \( \forall \nu_X(Y) \cdot \nu(\psi)(\alpha_{\nu_X}(\rho)) \), note that, by the satisfaction condition for the institution of quantified sentences over \( \mathcal{S} \), \( \langle \Sigma, \Gamma \rangle \models_{\Sigma} \forall Y \cdot \psi(\rho) \) implies \( \langle \Sigma', \Gamma' \rangle \models_{\Sigma'} \nu(\forall Y \cdot \psi(\rho)) \).\(^\dagger\) This means that \( \langle \Sigma', \Gamma' \rangle \models_{\Sigma'} \forall \nu_X(Y) \cdot \alpha_{\nu_Y}(\psi(\rho)) \) because, by the definition of the \( \nu \)-translation of quantified sentences, \( \nu(\forall Y \cdot \psi(\rho)) = \forall \nu_X(Y) \cdot \alpha_{\nu_Y}(\psi(\rho)) \). Moreover, according to the general properties of the morphism of substitution systems \( \langle \Psi_{\nu}, \kappa_{\nu}, \tau_{\nu} \rangle \) induced by \( \nu \), the square depicted below is commutative, from

\(^\dagger\) Recall that, since \( \nu \) is an \( \mathcal{L}P \)-morphism, the \( \nu \)-reduct of any \( \langle \Sigma', \Gamma' \rangle \)-model is a \( \langle \Sigma, \Gamma \rangle \)-model.
which we deduce that $\alpha_{\nu,Y}(\psi(\rho)) = \Psi_{\nu}(\psi)(\alpha_{\nu,X}(\rho))$.

$$\begin{array}{c}
\text{Sen}_{\Sigma}(X) \xrightarrow{\alpha_{\nu,X}} \text{Sen}_{\Sigma}(\Psi_{\nu}(X)) \\
\psi(\cdot) \Bigg| \xrightarrow{\Psi_{\nu}(\psi)(\cdot)} \Psi_{\nu}(\psi(\cdot)) \\
\text{Sen}_{\Sigma}(Y) \xrightarrow{\alpha_{\nu,Y}} \text{Sen}_{\Sigma}(\Psi_{\nu}(Y))
\end{array}$$

We thus conclude that $\langle \Sigma', \Gamma' \rangle \presub_{\Sigma}^{\text{lp}} \forall \Psi_{\nu}(Y) \cdot \Psi_{\nu}(\psi)(\alpha_{\nu,X}(\rho))$. ∎

Unlike the preservation property of Proposition 6.2.1, the reflection of solutions can only be guaranteed for those morphisms $\nu: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle$ that are conservative – in the sense that every model of the program $\langle \Sigma, \Gamma \rangle$ admits a $\langle \Sigma', \Gamma' \rangle$-expansion along $\nu$ – and that, moreover, lift substitutions.

**Definition 6.2.2** (Lifting substitutions). A morphism of logic programs $\nu: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle$ is said to lift substitutions if for every $\Sigma'$-substitution $\psi': \Psi_{\nu}(X) \rightarrow Y'$ there is a $\Sigma$-substitution $\psi: X \rightarrow Y$ such that $\Psi_{\nu}(\psi) = \psi'$.

Although the use of conservativity to support modularization is often considered as one of the fundamental principles of structuring logic programs or specifications [see e.g. ST11], this property is in general difficult to verify, as it is well known that even in the case of first-order logic it has no recursively axiomatized complete calculus [see MAH01]. Nevertheless, we can easily find additional assumptions that guarantee conservativeness. For instance, in the logic-programming language $\text{Jpres}$, for any morphism of programs $\nu: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle$ such that $\Gamma'$ and $\nu(\Gamma)$ are semantically equivalent (or, even more, equal), the property is independent of the set of clauses, and thus it suffices to consider $\nu$ as a signature morphism.2 In relational first-order logic, this means that all we have to check is that $\nu$ is injective on both operation and relation symbols [see e.g. Dia08]. The lifting-substitutions property further requires that $\nu$ is surjective on operation symbols.

**Fact 6.2.3.** In the generalized substitution system $\text{qf-FOL}_{1}^{\text{expr}}$, a signature morphism $\nu: \langle F, P \rangle \rightarrow \langle F', P' \rangle$ is conservative and lifts substitutions if and only if it is bijective on operation symbols and injective on relation symbols.

A similar result can be obtained for equational logic programming.

**Fact 6.2.4.** In $\text{qf-FOL}_{=}$, a signature morphism $\nu: \langle S, F \rangle \rightarrow \langle S', F' \rangle$ is conservative and lifts substitutions if and only if it is injective on all symbols and, for every sort $s \in S$ and operation symbol $\sigma' \in F'_{\nu^s_{\text{op}}(s)}$, there exists an operation symbol $\sigma \in F_{\nu^s_{\text{op}}(s)}$ such that $\nu^{\text{st}}(w) = w'$ and $\nu^{\text{op}}_{\nu^s_{\text{op}}(s)}(\sigma) = \sigma'$.

---

2 Alternatively, one could consider $\text{Jshape}$-morphisms of logic programs $\nu: P \rightarrow P'$ whose codomain $P'$ is semantically equivalent with translate $P$ by $\text{Sign}(\nu)$.
Note that, even though the conditions above may seem overly restrictive, they are often the best that can be achieved. For example, assume that \( v \) is the inclusion of first-order signatures \( \langle \{ \theta : 0 \}, \{ \text{add} : 3 \} \rangle \subseteq \langle \text{F_{Nat}}, \text{P_{Nat}} \rangle \), where \( \langle \text{F_{Nat}}, \text{P_{Nat}} \rangle \) is the signature of natural numbers discussed in Section 3.1.1, that \( \Gamma \) is the singleton set containing the clause \( \forall M \cdot \text{true} \Rightarrow \text{add}(M, 0, M) \), \( \Gamma' \) is \( v(\Gamma) \), and consider the query \( \exists X \cdot \text{add}(X, 0, X) \). Then the morphism \( v \) is conservative, and yet we may obtain solutions to the translated query \( v(\exists X \cdot \text{add}(X, 0, X)) \), such as \( X \mapsto s \ 0 \), that are not in the image of \( \Psi_v \).

**Proposition 6.2.5.** Consider a morphism \( v : \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle \) and a \( \Sigma \)-query \( \exists X \cdot \rho \). If \( v \) is conservative and lifts substitutions, then for every \( \langle \Sigma', \Gamma' \rangle \)-solution \( \psi' \) to \( v(\exists X \cdot \rho) \) there exists a \( \langle \Sigma, \Gamma \rangle \)-solution \( \psi \) to \( \exists X \cdot \rho \) such that \( \Psi_v(\psi) = \psi' \).

**Proof.** Let \( \psi' : \Psi_v(X) \rightarrow Y' \) be a \( \langle \Sigma', \Gamma' \rangle \)-solution to \( \exists \Psi_v(X) \cdot \alpha_{v,X}(\rho) \), that is to the \( v \)-translation of the query \( \exists X \cdot \rho \). Since the morphism \( v \) lifts substitutions, we know that there exists a \( \Sigma \)-substitution \( \psi : X \rightarrow Y \) such that \( \Psi_v(\psi) = \psi' \). Therefore, all we need to establish is that the signature of \( \Sigma \)-variables \( Y \) is conservative and that \( \langle \Sigma, \Gamma \rangle \modelslp \forall Y \cdot \psi(\rho) \).

The conservativeness of \( \psi \) and \( \Psi_v(Y) \): every \( \Sigma \)-model \( M \) admits a \( v \)-expansion \( M' \) (because \( v \) is conservative), which further admits a \( \Psi_v(Y) \)-expansion \( N' \) (because \( \Psi_v(Y) \) is conservative); then, based on the commutativity of the diagram below, \( \beta_{v,Y}(N') \) is a \( Y \)-expansion of \( M \).

\[
\begin{array}{ccc}
\text{Mod}(\Sigma) & \overset{\beta_{v,Y}}{\leftarrow} & \text{Mod}(\Sigma') \\
\downarrow v & & \downarrow v \\
\text{Mod}_\Sigma(Y) & \overset{\beta_{v,Y}}{\leftarrow} & \text{Mod}_\Sigma'(\Psi_v(Y))
\end{array}
\]

For the second property, note that, since \( \Psi_v(Y) \) is a \( \langle \Sigma', \Gamma' \rangle \)-solution to the query \( \exists \Psi_v(X) \cdot \alpha_{v,X}(\rho) \), we have \( \langle \Sigma', \Gamma' \rangle \modelslp \forall \Psi_v(Y) \cdot \Psi_v(\psi)(\alpha_{v,X}(\rho)) \). This means that \( \forall \Psi_v(Y) \cdot \alpha_{v,Y}(\psi(\rho)) \) is a semantic consequence of \( \langle \Sigma', \Gamma' \rangle \), because the sentence translations \( \alpha_{v,X} \triangleright \Psi_v(\psi) \) and \( \psi \triangleright \alpha_{v,Y} \) are equal. Thus, by the definition of the translation of quantified sentences, we deduce that

\[
\langle \Sigma', \Gamma' \rangle \modelslp \forall Y \cdot \psi(\rho).
\]

Suppose now that \( M \) is a model of the program \( \langle \Sigma, \Gamma \rangle \). Since the morphism \( v \) is conservative, there exists a \( v \)-expansion \( M' \) of \( M \) such that \( M' \modelslp \langle \Sigma', \Gamma' \rangle \). As a result, \( M' \modelsqs \forall Y \cdot \psi(\rho) \), which further implies, by the satisfaction condition for \( v \), that \( M \modelsqs \forall Y \cdot \psi(\rho) \). Therefore, \( \langle \Sigma, \Gamma \rangle \modelslp \forall Y \cdot \psi(\rho) \). \( \square \)
6.3 COMPUTING ANSWER SUBSTITUTIONS

From an operational point of view, it is also useful to investigate the preservation and the reflection of computed answers (to given queries) along morphisms of programs, as this may enable us to overcome some of the limitations imposed by query-completeness or conservativeness. For this purpose, we will only consider morphisms that are simple, that is morphisms of logic programs $\nu: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle$ for which $\nu(\Gamma) \subseteq \Gamma'$.

Let us first notice that trivial queries are both preserved and reflected (under mild additional assumptions) along every signature morphism $\varphi$; this follows from the satisfaction condition for the morphism of substitution systems $\langle \varphi_\varphi, \kappa_\varphi, \tau_\varphi \rangle$ determined by $\varphi$ in combination with the model-amalgamation property of the generalised substitution system $\mathcal{GS}$ or, in the case of reflection, with the conservativeness of $\varphi$.

**Fact 6.3.1.** For every morphism of signatures $\varphi: \Sigma \rightarrow \Sigma'$, the translation of every trivial $\Sigma$-query $\exists Y \cdot \top$ is a trivial query as well. Moreover, if $\varphi$ is conservative, then a query $\exists Y \cdot \top$ is trivial whenever $\varphi(\exists Y \cdot \top)$ is trivial.

**Lemma 6.3.2.** For every simple morphism of programs $\nu: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle$, every (one-step) $\Gamma$-derivation $\exists X_1 \cdot \rho_1 \rightarrow_{\Gamma, \beta_1} \exists X_2 \cdot \rho_2$ determines a $\Gamma'$-derivation $\nu(\exists X_1 \cdot \rho_1) \rightarrow_{\Gamma, \psi_\nu(\beta_1)} \nu(\exists X_2 \cdot \rho_2)$.

**Proof.** Assume that $\exists X_2 \cdot \rho_2$ is a query derived by resolution from $\exists X_1 \cdot \rho_1$ and $\Gamma$ using the computed substitution $\theta_1: X_1 \rightarrow X_2$. It follows that there exists a clause $\forall Y_1 \cdot \gamma_1 \in \Gamma$ and a substitution $\psi_1: Y_1 \rightarrow X_2$ such that $\theta_1(\rho_1), \psi_1(\gamma_1) \not\models X_2 \cdot \rho_2$. Then, by the functoriality of $\models$, we know that $\alpha_{\nu,X_2}(\theta_1(\rho_1)), \alpha_{\nu,X_2}(\psi_1(\gamma_1)) \not\models \Sigma' \psi_\nu(X_2) \alpha_{\nu,X_2}(\rho_2)$. This allows us to deduce, based on the naturality of $\alpha_{\nu}$, that

$$\Psi_\nu(\theta_1)(\alpha_{\nu,X_1}(\rho_1)), \Psi_\nu(\psi_1)(\alpha_{\nu,Y_1}(\gamma_1)) \not\models \Sigma' \psi_\nu(X_2) \alpha_{\nu,X_2}(\rho_2).$$

Therefore, the translated query $\exists \Psi_\nu(X_2) \cdot \alpha_{\nu,X_1}(\rho_2)$ can be derived by resolution from $\exists \Psi_\nu(X_1) \cdot \alpha_{\nu,X_1}(\rho_1)$ and $\forall \Psi_\nu(Y_1) \cdot \alpha_{\nu,Y_1}(\gamma_1)$ using the computed substitution $\Psi_\nu(\theta_1)$. By the definition of the translation of quantified sentences along signature morphisms, we further deduce that $\nu(\exists X_2 \cdot \rho_2)$ can be derived by resolution from $\nu(\exists X_1 \cdot \rho_1)$ and $\nu(\forall Y_1 \cdot \gamma_1)$ using the computed morphism $\Psi_\nu(\theta_1)$. We can thus conclude, based on the fact that $\nu$ is simple, that $\nu(\exists X_2 \cdot \rho_2)$ can be derived from $\nu(\exists X_1 \cdot \rho_1)$ and $\Gamma'$.

The preservation of computed answers along simple morphisms of logic programs is a consequence of the preservation of trivial queries and the reflection of the retraction of computed answers.
proves follows by repeated applications of Lemma 6.3.2 and by Fact 6.3.1.

**Proposition 6.3.3.** Let \( v: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle \) be a simple morphism of logic programs and \( \theta: X \rightarrow Y \) a computed \( \langle \Sigma, \Gamma \rangle \)-answer to a \( \Sigma \)-query \( \exists X \cdot \rho \). Then the substitution \( \Psi_v(\theta) \) is a computed \( \langle \Sigma', \Gamma' \rangle \)-answer to \( v(\exists X \cdot \rho) \). \( \square \)

As in the case of solutions, the reflection of computed answers relies on additional hypotheses, which correspond here to the reflection of final rules.

**Definition 6.3.4 (Reflection of final rules).** A simple morphism of programs \( v: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle \) reflects final (goal-directed) rules if for every conservative signature of \( \Sigma \)-variables \( X \), \( X \)-query \( \rho \), and trivial \( \Psi_v(X) \)-query \( \Gamma' \) such that

\[
\alpha_v, X(\rho), \Psi_v(X)(\Gamma') \not\vDash_{\Sigma', \Psi_v(X)} \Gamma'
\]

there exists a trivial \( X \)-query \( \top \) such that

\[
\rho, X(\Gamma) \vDash_{\Sigma, X} \top.
\]

It is rather straightforward to see that the reflection of final rules is satisfied by most simple morphisms of logic programs used for structuring purposes. For instance, in \( (\mathcal{FO} \mathcal{L}_{\leq 1})^{\text{pres}} \), a simple morphism of logic programs \( v: \langle \langle F, P \rangle, \Gamma \rangle \rightarrow \langle \langle F', P' \rangle, \Gamma' \rangle \) reflects final goal-directed rules if it does not introduce new information concerning the old predicates: for every clause \( \forall Y \cdot H \Rightarrow \pi(t'_1, \ldots, t'_n) \) in \( \Gamma' \setminus v(\Gamma) \), \( \pi' \) is a relation symbol in \( P' \setminus v_{\text{rel}}(P_n) \).

**Lemma 6.3.5.** Let \( v: \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle \) be a simple morphism of programs such that \( \text{Sign}(v): \Sigma \rightarrow \Sigma' \) is conservative. The following statements are equivalent:

1. For every \( \Sigma \)-query \( \exists X \cdot \rho \) and substitution \( \theta: X \rightarrow Y \), \( \theta \) is a computed \( \langle \Sigma, \Gamma \rangle \)-answer to \( \exists X \cdot \rho \) whenever \( \Psi_v(\theta) \) is a computed \( \langle \Sigma', \Gamma' \rangle \)-answer to \( v(\exists X \cdot \rho) \).
2. The morphism \( v \) reflects final goal-directed rules.

**Proof.**

1 \( \Rightarrow \) 2. Suppose \( X \) is a conservative signature of \( \Sigma \)-variables, \( \rho \) is an \( X \)-query, and \( \Gamma' \) is a trivial \( \Psi_v(X) \)-query such that \( \alpha_v, X(\rho), \Psi_v(X)(\Gamma') \not\vDash_{\Sigma', \Psi_v(X)} \Gamma' \). By Proposition 3.3.30, it follows that \( \exists \Psi_v(X) \cdot \alpha_v, X(\rho) \rightarrow_{v, \Omega_v(X)}^* \exists \Psi_v(X) \cdot \Gamma' \). Since \( X \) is conservative and \( \mathcal{F} \) has weak model-amalgamation, we deduce that \( \Psi_v(X) \) is also conservative, and thus that \( \exists \Psi_v(X) \cdot \Gamma' \) is trivial. Therefore, by hypothesis, there exists a trivial \( X \)-query \( \top \) such that \( \exists X \cdot \rho \rightarrow_{v, \Omega_v(X)}^* \exists X \cdot \top \). As a result, by Proposition 3.3.30, we obtain \( \rho, X(\Gamma) \vDash_{\Sigma, X} \top. \)
Let us now consider \( \exists X \cdot \rho \) to be a \( \Sigma \)-query and \( \theta \) to be a substitution for which \( \Psi_\nu(\theta) \) is a computed answer to \( \nu(\exists \Sigma \cdot \rho) \), meaning that there exists a trivial \( \Psi_\nu(Y) \)-query \( \top \) such that \( \nu(\exists \Sigma \cdot \rho) \rightarrow^*,_{\Psi_\nu(\theta)} \exists \Psi_\nu(Y) \cdot \top \).

By Proposition 3.3.30, \( \Psi_\nu(\theta)(a_\nu(X(\rho))), \Psi_\nu(Y)(\Gamma') \vDash^*_{\Sigma, \Psi_\nu(Y)} \top \), from which we deduce, by the naturality of \( a_\nu \), that \( \nu(Y(\rho)), \Psi_\nu(Y)(\Gamma') \vDash^*_{\Sigma, \Psi_\nu(Y)} \top \).

Moreover, since both \( \text{Sign}(\nu) \) and \( \Psi_\nu(Y) \) are conservative, it follows that \( Y \) is conservative as well. This means that we can use the reflection of final goal-directed rules to derive the existence of a trivial \( Y \)-query \( \top \) such that \( \nu(\rho), Y(\Gamma) \vDash^*_{\Sigma, \nu} \top \). By applying Proposition 3.3.30 one last time, we conclude that \( \theta \) is a computed \( \langle \Sigma, \Gamma \rangle \)-answer to \( \exists X \cdot \rho \).

Note that, as opposed to solutions, in the case of computed answers we are able to fully characterize their reflection along morphisms of logic programs.

**Proposition 6.3.6.** Let \( \nu \colon \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle \) be a simple morphism of logic programs, \( \exists X \cdot \rho \) a \( \Sigma \)-query, and \( \theta' \) a computed \( \langle \Sigma', \Gamma' \rangle \)-answer to \( \nu(\exists X \cdot \rho) \). If \( \text{Sign}(\nu) \) is conservative, and if \( \nu \) lifts substitutions and reflects final goal-directed rules, there is a computed \( \langle \Sigma, \Gamma \rangle \)-answer \( \theta \) to \( \exists X \cdot \rho \) such that \( \Psi_\nu(\theta) = \theta' \).

Propositions 6.3.3 and 6.3.6 enable the computation of all solutions to certain queries even in situations in which the given logic program is not query-complete, or in which it constitutes the result of an extension of logic programs that is not known to be conservative.

**Corollary 6.3.7.** Consider a simple morphism \( \nu \colon \langle \Sigma, \Gamma \rangle \rightarrow \langle \Sigma', \Gamma' \rangle \) between programs \( \langle \Sigma, \Gamma \rangle \) and \( \langle \Sigma', \Gamma' \rangle \), and a \( \Sigma \)-query \( \exists X \cdot \rho \) that admits an identity in \( \Gamma \).

- If \( \nu \) is conservative and lifts substitutions, and if \( \langle \Sigma, \Gamma \rangle \) is query-complete, every \( \langle \Sigma', \Gamma' \rangle \)-solution to \( \nu(\exists X \cdot \rho) \) is also a computed \( \langle \Sigma', \Gamma' \rangle \)-answer to \( \nu(\exists X \cdot \rho) \).
- If \( \langle \Sigma', \Gamma' \rangle \) is query-complete, \( \text{Sign}(\nu) \) is conservative, and \( \nu \) lifts substitutions and reflects final goal-directed rules, then every \( \langle \Sigma', \Gamma' \rangle \)-solution to \( \nu(\exists X \cdot \rho) \) is the image under \( \nu \) of a \( \langle \Sigma, \Gamma \rangle \)-solution to \( \exists X \cdot \rho \).

The schematic representation in Figure 6.1 summarizes the various relationships between solutions and computed answers in connection with morphisms of logic programs. To this end, we consider \( \nu \) to be a morphism between logic programs \( \langle \Sigma, \Gamma \rangle \) and \( \langle \Sigma', \Gamma' \rangle \), and \( \exists X \cdot \rho \) to be a \( \Sigma \)-query.
Figure 6.1. Relationships between solutions and computed answers

1 by Theorem 3.3.24
2 by Theorem 3.3.25, based on the query-completeness of $\langle \Sigma', \Gamma' \rangle$ and on the assumption that the translated query $\nu(\exists X \cdot \rho)$ admits an identity in $\Gamma'$
3 by Theorem 3.3.25, based on the query-completeness of $\langle \Sigma, \Gamma \rangle$ and on the assumption that the original query $\exists X \cdot \rho$ has an identity in $\Gamma$
4 by Proposition 6.2.1
5 by Proposition 6.2.5, based on the conservativeness of $\nu$ and on the lifting of substitutions
6 by Proposition 6.3.3, based on the assumption that $\nu$ is simple
7 by Proposition 6.3.6, based on the assumptions that $\nu$ is simple, it lifts substitutions and reflects final goal-directed rules, and its underlying signature morphism is conservative
CONCLUSIONS AND FURTHER WORK

In this thesis, we have advanced an abstract axiomatic theory of logic programming by identifying and examining in an institution-theoretic setting two of the most basic principles of the paradigm: (a) the fact that each logic program has a rigorous mathematical semantics given by a class of models (and often by a ‘standard’ model of that class) that determines the specific set of queries that can be positively answered, and (b) the existence of a sound (and in some cases complete) goal-directed procedure for computing answer-substitutions that confirm the validity of the positive answer received by a query. In this way, the present study unifies the relational and the equational variants of logic programming, and we can expect it to integrate with ease many other derived forms of the paradigm, such as constraint [see Dia00] or behavioural [see GMK02] logic programming, which share many similarities with the equational variant presented in Section 4.1.

The logic-programming semantics of services discussed in Section 5.2 provides us a significantly different form of logic programming – even though the logic programs (known in this case as repositories) and their corresponding operational semantics are defined similarly to their relational counterparts. This is mainly due to the fact that the signatures of variables (formalized as labelled hypergraphs) can no longer be treated as extensions of signatures (which provide the structures to be used as labels for the hypergraphs that underlie the signatures of variables). Consequently, service-oriented substitutions cannot be captured by the institution-independent concept of substitution considered in [Dia04], nor can they be expressed as generalized forms of signature morphisms as in [GFO12; MKMip].

To be more precise, the theory of services that we have developed in this thesis is grounded on a declarative semantics of service clauses defined over a novel logical system of orchestration schemes. The structure of the sentences and of the models of this logical system varies according to the orchestration scheme under consideration. For example, when orchestrations are defined as asynchronous relational networks over the institution $\mathbb{ALTL}$, we obtain
sentences as linear-temporal-logic sentences expressing properties observed at given interaction points of a network, and models in the form of ground orchestrations of Muller automata. Other logics (with corresponding model theory) could have been used instead of the automata-based variant of linear temporal logic, more specifically any institution such that (a) the category of signatures is (finitely) cocomplete; (b) there exist cofree models along every signature morphism; (c) the category of models of every signature has (finite) products; and (d) model homomorphisms reflect the satisfaction of sentences. Moreover, the formalism used in defining orchestrations can change by means of morphisms of orchestration schemes. We could consider, for instance, an encoding of the hypergraphs of processes and connections discussed in Section 5.1.2 into graph-based structures that are similar to those presented in [FL13a]; or we could change their underlying institution by adding new temporal modalities (along the lines of Example 5.2.2) or by considering other classes of automata, like the closed reduced Büchi automata used in [AS87; FL13b]. This encourages us to further investigate aspects related to the heterogeneous foundations of service-oriented computing based on the proposed logical system of orchestration schemes.

In the more general context of abstract logic-programming languages, our efforts have focused mainly on the development of a simple yet sufficiently rich theoretical framework to allow the investigation of properties related to the satisfaction of quantified sentences, the generalization of Herbrand’s theorem and, moreover, the definition of a sound and (conditionally) complete procedure for computing solutions to queries. This procedure relies on exploring a potentially infinite search space of queries, related through substitutions computed by means of resolution, in search of queries that are trivial, i.e. known to admit the simplest possible solutions. Its implementation is not complete because we do not commit to any particular search strategy, which could make use, for example, of most general unifiers and backtracking. However, it should be noted that under the present formalization of the search space, any such strategy would be sound, and even complete if it ensured that the reachability of all trivial queries is maintained.

Thus, apart from the obvious need to consider various other forms of logic programming, a very interesting direction for future research is to further formalize and examine the notion of strategy, especially in connection with the modularization of logic programs. To that end, one would have to take into account the fact that the sets of clauses associated with logic programs are often structured, in the sense that certain clauses take precedence over others in the computation of the next (derived) query to be solved. Moreover,
given strategies could make use only of most general unifiers, hence imposing additional restrictions on computed substitutions. All these aspects could be dealt with abstractly by narrowing the search space of queries. In that case, the challenge lies in determining the basic conditions under which properties such as the preservation of computed answers still hold.

Another open problem of practical importance is the development of an appropriate concept of map of logic-programming languages to capture, for example, the encoding of relational logic programming into its equational correspondent based on the representation of relations as Boolean-valued operations [see e.g. Dia08]. Even though from a denotational perspective we obtain an immediate answer in the form of the notion of morphism of generalized substitution systems (suggested in Definition 3.2.6), from an operational point of view the answer does not appear to be equally obvious since different logic-programming frameworks may be founded on highly different kinds of goal-directed rules.
