Abstract

Police use of TASER can have serious consequences; therefore, it is important to examine any modifiable operational factors that impact an officer's decision to use TASER. As previous research has identified a potential relationship between crewing and TASER use, a systematic review was undertaken to explore which factors might impact police use of TASER by the Police Service of England and Wales, including officer crewing levels.

Over 14,000 records were screened, resulting in a final sample of 20 studies; with findings indicating that further research is needed to better understand TASER use and ensure policy is well informed and appropriate.

Key words

Police, TASER, Crewing, Conducted Energy Device.

Introduction

Since the introduction of TASER (a type of Conducted Energy Device) into the Police Service of England and Wales (PSEW) in the early 2000s, police use of TASER has increased consistently and considerably. According to official Home Office statistics, TASER was used just over 34 thousand times by police in England and Wales between April 2021 and March 2022, approximately double the rate of use compared to the year ending March 2018 (Home Office, 2022a).

Although a review conducted by the Defence Scientific Advisory Council Sub-Committee on the Medical Implications of Less-Lethal Weapons (DOMILL) in 2008 concluded that *'the risk of death or serious injury from use of the M26 and X26 Tasers within ACPO Guidance and Policy is very low,'* (p.19), TASER has been linked to a number of harmful side-effects, including (but not limited to); puncture wounds, burns from electrical discharge, secondary injuries caused by falls or other uncontrolled movements associated with neuromuscular incapacitation and the subsequent loss of posture, as well as adverse effects on the heart, circulation, and respiratory system in those with pre-existing medical conditions (Childers, Chan & Vilke, 2020; DOMILL, 2012; Kroll, 2019; TASER International, 2013; Scientific Advisory Committee on the Medical Implications of Less-Lethal Weapons, 2016). Previous research has also indicated that TASER can impair cognitive function for up to an hour after exposure (Kane and White, 2015), which could have serious implications for whether or not a subject can understand their rights when cautioned or follow post-exposure instructions.

Given the above, perhaps it is somewhat surprising that, until recently, there has been little interest in the decision to use TASER, and to what extent, within the UK academic field. Since 2016, there have only been two key explorations into TASER use within English and Welsh police (i.e. Dymond, 2016 and 2018, and; Quinton et al, 2020), both of which explored

1
2
3 and identified several factors that were significantly related to the use of TASER by
4
5 examining mandatory use of force records generated from English police forces. A
6
7 mandatory 'use of force' record is generated when an officer, or member of police staff, uses
8
9 force against a member of the public,¹ and is a formal record of key incident characteristics.
10
11 This includes information on, situational and subject characteristics, interactional elements,
12
13 officer factors, and any resulting injuries to the subjects and/or officers in attendance.
14
15

16
17 Whilst all the above are important factors to examine, those that can be easily
18
19 modified and that are within the Police Services' sphere of operational control may be of
20
21 particular interest, as these could offer valuable opportunities or mechanisms for moderating
22
23 the use of TASER. Given that subject characteristics and, to a large extent, officer
24
25 characteristics, are either fixed (e.g. gender and ethnicity) or outside the normal control of
26
27 police operations (e.g. incident location), situational and organisational characteristics may be
28
29 the most promising and practical areas to explore for potential modifiers.
30
31

32
33 The only situational factor that was examined by these two key academic
34
35 explorations, that also sits firmly within the sphere of operational control, was the number of
36
37 officers present during the incident. However, when inspecting their findings, the authors'
38
39 results were in conflict; with Dymond (2016, 2018) finding no association between the
40
41 number of officers present and TASER use, and Quinton et al. (2020) finding that officers
42
43 were more likely to discharge their TASER when they were single-crewed (i.e. working
44
45 alone).
46
47

48
49 Given the potential for harm associated with TASER and the increasing frequency
50
51 with which TASER is used by the Police Service of England and Wales, it is imperative that
52
53

54
55
56
57 ¹ Including, but not limited to: Batons, dog deployment or bite, firearms, handcuffing, irritant
58
59 spray, limb/body restraints, spit and bite guards, shields, TASER, and unarmed skills.
60

1
2
3 we extend our current understanding of when, and in which circumstances, officers are more
4
5 or less likely to use TASER – paying particular attention to factors that are more likely to fall
6
7 within the operational sphere of control, such as officer crewing.
8
9

10 This systematic literature review aims to provide the first step in this exploration by
11
12 gathering and synthesizing all the currently available evidence regarding which factors might
13
14 impact an officer's decision to use TASER within the PSEW, and, more specifically, whether
15
16 officer crewing affects TASER use.
17
18
19

20 **Method**

21 **Search process**

22
23
24
25 The protocol for this systematic review was registered on PROSPERO - International
26
27 Prospective Register of Systematic Reviews (registration number: CRD42019151366), and
28
29 based on PRISMA-P checklist (Shamseer et al, 2015).
30
31

32 A comprehensive literature search was performed in December 2019, and a
33
34 supplementary search was conducted in October 2021 for the years 2019-21 to ensure the
35
36 review could account for more recent publications. The records included in this review are all
37
38 articles available up to (and including) October 2021, as well as a single organisational report
39
40 that was informally identified via practitioner recommendation (i.e. Quinton et al., 2020).
41
42

43 Search terms for the four key concepts are listed in Table I, and a staged matrix
44
45 design was used to combine search terms to ensure a robust search. Stage one of the matrix
46
47 design required the reviewer to search for all key concepts together; Stage two required the
48
49 reviewer to search for all possible combinations of three concepts; Stage three required the
50
51 reviewer to search for all possible combinations of two concepts, and finally; Stage four of
52
53 the matrix design required the reviewer to search the reference list of all identified reports
54
55 and articles for additional studies that fit the eligibility criteria described below.
56
57
58
59
60

1
2
3 For papers to be eligible, they had to be: a) original empirical research, b) written in
4 English, c) relevant to the review aims described in the introduction, d) include participants
5 from the policing population of England and Wales, or other countries with similar policing
6 principles (e.g. those that have been notably influenced the British approach to policing
7 referred to as 'policing by consent'),² and e) include one of the following as a key outcome
8 measure or the main phenomenon of interest; the frequency and type of TASER use, the
9 position of TASER use within sequential use of force situations, or the reasons for TASER
10 use.
11
12

13 [ENTER TABLE I AROUND HERE]
14

15 The PRISMA diagram (Figure I) details the results of the literature search, screening,
16 and selection processes. In total, the initial searches identified 14,447 published and
17 unpublished records. After duplicates were removed, 13,399 articles were screened against
18 the criteria above, resulting in the retention of 20 records and forming the basis of this
19 review.
20
21

22 [ENTER FIGURE I AROUND HERE]
23

24 **Quality Assessment**

25 The following three quality appraisal checklists used by the National Institute for Health
26 and Care Excellence (2012) in their development of Public Health Guidance were used to
27 assess the quality of the available research to help inform interpretation of the findings: The
28 quality appraisal checklist for quantitative intervention studies;³ the quality appraisal
29
30
31
32
33
34
35
36
37

38 ² This includes parts of the Commonwealth, such as Canada, Australia and New Zealand, as
39 well as the United States of America (Archbold, 2013; Buttle, 2010; de Lint, 2004;
40 Goldsmith, 2001).

41 ³ For more information please see:

3 checklist for quantitative studies reporting correlations and associations,⁴ and; the quality
4
5 appraisal checklist for qualitative studies.⁵
6
7

8 A fifth of the papers (n=4) identified via the searches conducted in December 2019 were
9
10 independently rated by two reviewers, who then discussed and agreed the ratings together.
11
12 After this, another 15% of papers (n=3), one from each type of quality assessment, were rated
13
14 independently by the reviewers to ascertain inter-rater reliability. Given that the interrater
15
16 agreement across papers were found to be moderate or higher (please see Table II), the scores
17
18 from the primary reviewer were retained as the final scores for those three papers and the
19
20 remaining papers were scored by the primary reviewer alone.
21
22

23
24 [ENTER TABLE II AROUND HERE]
25

26 **Data management, extraction and synthesis**

27
28 Data were mined from the review sample using a bespoke data extraction form
29
30 developed by the primary reviewer and based on the eight categories covered in the Cochrane
31
32 data collection form for intervention reviews for randomized control trials (2019). For
33
34 studies that presented a number of results, only those that are relevant to this review were
35
36 extracted and included. Due to the expected heterogeneity of the studies included in this
37
38 review a quantitative synthesis/meta-analysis was not included. A summary iteration of the
39
40 extraction sheet can be found below:
41
42
43

44
45 [ENTER TABLE III AROUND HERE]
46

47 Once data had been extracted from the studies, the information contained within the
48
49 data extraction table was subject to thematic analysis loosely based on the six-phase method

1
2
3 by Braun and Clarke (2006). Thematic analysis was chosen as it allows a flexible and
4
5 accessible approach to analysis that can span the inductive - deductive divide, and would
6
7 allow the review to: a) identify gaps in the existing literature, and b) to explore common
8
9 themes across the studies in line with the aims of this review.
10
11

12 Although no assumptions about the themes that might emerge were made, the data
13
14 had been extracted before analysis via a bespoke template that was made to specifically
15
16 address the literature review questions. As such, some decisions on what data to include in
17
18 the analyses had already been made; thus, the approach is semi-deductive in nature. In order
19
20 to answer the aims of the research, analysis focused on exploring the variables that were
21
22 measured as outcomes, predictors or controls by the research papers.
23
24
25
26
27

28 **Results**

29 A brief overview of key study characteristics is presented before systematically
30
31 examining the themes that emerged with regard to factors relating to TASER use.
32
33

34 **Overview of key study characteristics**

35
36 Most studies were conducted in the United States of America (USA; n=15). Only
37
38 three studies used a policing population from England and Wales, and the final two were
39
40 Antipodean. In the most part, studies were observational in nature (n=18), with only two
41
42 studies falling into a category that could be classed as an experimental or quasi-experimental
43
44 field design. Overall, 17 studies were quantitative and just three were qualitative, with
45
46 official use of force forms and/or officer personnel files being the most frequently used
47
48 source of data (n=13).
49
50
51

52 Although the quality assessments were fairly positive overall, the geographical
53
54 location of the sample populations meant that the majority of studies were rated higher for
55
56 internal than external validity.
57
58

59 **Key outcome variables of interest**

60

1
2
3 Although 19 out of the 20 studies specifically examined the frequency of TASER use
4 as a key outcome measure or the main phenomenon of interest (all except Sierra-Arévalo,
5 2019), the way in which ‘frequency’ was defined differed greatly from study to study. For
6
7
8
9
10 example, Ready and White (2011) defined frequency at a personal level by identifying and
11

Although 19 out of the 20 studies specifically examined the frequency of TASER use as a key outcome measure or the main phenomenon of interest (all except Sierra-Arévalo, 2019), the way in which ‘frequency’ was defined differed greatly from study to study. For example, Ready and White (2011) defined frequency at a personal level by identifying and categorizing individual officers in accordance with the frequency that they used TASER during the previous year; classifying them as either a non-user (those that had not fired their TASER), users (one to two uses) and high frequency user (three or more uses). However, Crow and Adrion (2011) counted frequency of TASER use during an incident; Bishopp, Klinger and Morris (2015) compared instances of TASER use over time, and; Brandl and Strohshine (2017) compared instances of TASER with other types of force, such as firearms or oleoresin capsicum spray (OCS). Other studies provided descriptive accounts of TASER use without a comparator (e.g. White & Ready, 2007), and in some papers, ‘use’ of TASER was not explicitly defined.

58
59
60

In practice, the use of TASER can be much more nuanced than merely being fired or not. The PSEW, for example, currently records seven different types of TASER use; four of which are classed as ‘non-discharge uses’ as no electricity is intended to be discharged into the subject (i.e., drawn, aimed, arced and red-dot), and the remaining three are categorized as ‘discharge uses’ (i.e., drive-stun, fired, and angle drive-stun; Home Office, 2019). Only six papers (Boehme et al., 2021; den Heyer, 2020; Dymond, 2016; Escalante, 2020; Quinton et al., 2020; Thomas et al., 2010), however, defined more than one type of TASER use; and even then, the distinctions were only between the TASER being fired, and drawn but not fired (with the exception of den Heyer, 2020).

54
55
56
57
58
59
60

Police use of force does not usually happen in isolation, but rather as part of a complex interpersonal interaction between an officer and a member of the public. This means that it is entirely possible that an officer might use more than one *type* of force during an

1
2
3 exchange. As such, capturing all types of force used, and the order in which they are used,
4
5 could be important variables when evaluating the use of TASER. Nonetheless, only four of
6
7 the 20 papers examined the sequential position of TASER within incidents where more than
8
9 one type of force was used (Brandl & Stroschine, 2017; Gau et al., 2010; Hine et al., 2018; Lin
10
11 & Jones, 2010).

12
13
14
15 Finally, only the three qualitative studies (Escalante, 2020; Hine et al., 2018; Sierra-
16
17 Arévalo, 2019), discussed officers' reasons for using TASER specifically (rather than their
18
19 reasons for using force), and the scope of these explorations remained extremely small.

20 21 22 **Emergent or related variables of interest**

23
24 From the 20 studies included in this review, 30 variables were identified through
25
26 analysis of the data extraction table, all of which could be grouped into one of the following
27
28 three global factor themes: 1) Situational, contextual, and interactional elements 2) Subject
29
30 characteristics, and 3) Officer factors.

31
32
33 Only variables that were explored by four or more studies (and/or four separate
34
35 datasets) were included in this review as a sub-theme. Those that were explored by only three
36
37 or fewer were automatically considered to be factors of *indeterminant influence*, due to lack
38
39 of evidence, and removed from the final thematic evaluation.

40
41
42 Variables that were explored by four or more studies (and/or at least four separate
43
44 data sets), which predominantly found no associations between TASER use and the factor
45
46 sub-theme under examination, were considered to be factors of *unlikely influence* and were
47
48 also removed from the final thematic evaluation.

49
50
51 Factors of *uncertain influence* were variables that had been explored by four or more
52
53 studies (and/or at least four separate data sets) and which had disparate findings in relation to
54
55 whether or not an association was found between TASER use and the factor sub-theme under
56
57 examination. Finally, for a factor sub-theme to be considered as a *potentially influencing*
58
59
60

1
2
3 *factor*, the variable must have been explored by four or more studies (and/or at least four
4 separate data sets), which predominantly found some sort of relationship between TASER
5 use and the sub-theme under examination.
6
7
8

9
10 Only factors of *uncertain influence* or *potentially influencing* factors were included in
11 the final thematic evaluation; resulting in the retention of 18 factor sub-themes that can be
12 directly mapped onto the three global factor themes identified above. A brief narrative
13 exploration of each of these factor themes, grouped according to their global factor theme
14 will be presented hereafter, (please see Table IV for additional information).
15
16
17
18
19
20

21 **Global Factor Theme One: Situational, contextual, and interactional elements**

22 This global theme consisted of the following seven factor subthemes which are examined in
23 turn below: (a) Level of subject resistance/compliance; (b) Local TASER and use of force
24 policies; (c) Number of subjects and/or bystanders; (d) Location; (e) Type of
25 call/offence/incident; (f) Number of officers present; and (g) Time of day and/or lighting.
26
27
28
29
30
31

- 32
33 a) *Level of subject resistance/compliance*: Fifteen studies assessed this factor, ten of
34 which used inferential statistics to explore the data. All bar one of the quantitative
35 studies that used inferential statistics found an association between subject
36 resistance/compliance and TASER use. The direction of this association, however,
37 was less consistent. Some studies found that TASER use was associated with higher
38 levels of resistance or 'active' resistance, whilst others indicated that TASER was
39 associated with lower levels of resistance.
40
41
42
43
44
45
46
47
48
49 b) *Local TASER and use of force policies*: Eight studies assessed this factor, seven of
50 which were inferential studies. All bar one of the studies that used inferential statistics
51 found an association between local TASER policies and TASER use, and the findings
52 suggested that officers changed their use of TASER to comply with local policy
53 changes.
54
55
56
57
58
59
60

- 1
2
3 c) *Number of subjects and/or bystanders*: Five studies assessed this factor, three of
4 which were multivariate studies. All three of the studies that used inferential statistics
5 found an association between the number of subjects/bystanders and the use of
6 TASER. The findings from these studies suggest that officers are more likely to use
7 TASER when subjects are alone. These findings were also supported by the
8 qualitative study, which suggested that the officer to subject ratio (i.e., the number of
9 officers present compared to the number of subjects) was an overt and pragmatic
10 influence over force decision.
11
12 d) *Location*: Five studies assessed this factor, including one multivariate study. The
13 multivariate study found an association between incident location and TASER use;
14 with TASER use being more likely in dwellings, and less likely in police or medical
15 settings. This was supported by the findings from the qualitative study which also
16 identified location as an emergent issue; with officers indicating that that both open
17 and enclosed spaces posed contextual constraints on their use of force choices.
18
19 e) *Type of call/offence/incident*: Five studies assessed this factor, three of which were
20 multivariate studies. Two out of the three multivariate studies found an association
21 between type of call/offence/incident and TASER use, and one did not.
22
23 f) *Number of officers present*: Seven studies assessed this factor, four of which used
24 inferential statistics to explore the data. However, it must be noted that two of the
25 studies used the same data set. Of the four multivariate studies, two found an
26 association between number of officers present and TASER use, and two did not.
27
28 g) *Time of day and/or lighting*: Four studies assessed this factor, all of which were
29 multivariate studies. Three out of the four multivariate studies found no statistically
30 significant associations between TASER use and time of day and/or lighting, and the
31 remaining study found that incidents occurring at night were more likely to be 'high

1
2
3 risk' for TASER use and, conversely, that daytime incidents were more likely to be at
4
5 'lower risk' of TASER use.
6
7

8 **Global Factor Theme Two: Subject characteristics**

9

10 This global theme consisted of the following six factor subthemes which are examined in turn
11
12 below: (a) Gender; (b) Perceived mental health status; (c) Ethnicity; (d) Intoxication; (e)
13
14 Subject armed or believed to be armed with a weapon; and (f) Age.
15
16

17 a) *Gender*: Ten studies assessed this factor, seven of which were multivariate studies.
18

19 All but one of the multivariate studies that used inferential statistics found an
20
21 association between subject gender and TASER use. The findings from these studies
22
23 indicated that TASER was more likely to be used against male subjects than female
24
25 subjects. This was supported by the findings from the qualitative study which found
26
27 officers considered female subjects as **less** threatening and consequently did not feel
28
29 as much force was necessary.
30
31
32

33 b) *Perceived mental health status*: Seven studies assessed this factor, five of which were
34
35 multivariate studies. All five of the multivariate studies found an association between
36
37 the perceived mental health and wellbeing of a subject and the use of TASER. More
38
39 specifically, all five found that TASER was more likely to be used against subjects
40
41 that were considered to have a mental health issue, a mental **'disability,'** mental
42
43 **'instability,'** appeared 'mentally disturbed,' and/ or mental health was otherwise
44
45 considered to be an impact factor.
46
47
48

49 c) *Ethnicity*: Ten studies examined this factor; eight of which were multivariate in
50
51 nature. The findings, however, were far from convergent. Half of the multivariate
52
53 studies found an association between ethnicity and TASER use, whilst the other half
54
55 found no such associations. Studies that found associations identified several minority
56
57 communities that might be at higher risk of TASER being used against them (e.g.
58
59
60

1
2
3 those from Black or Hispanic communities), and one that might be at lower risk (i.e.,
4 those from Asian communities).
5
6

- 7
8 d) *Intoxication*: Eight studies assessed this factor, five of which were multivariate
9
10 studies. Three multivariate studies found an association between subject intoxication
11 and TASER use, whilst four found no such associations. It is worth noting that the
12 findings from these studies were divergent both within and between types of
13 intoxication (i.e., drugs / alcohol).
14
15
16
17
18
19 e) *Subject armed or believed to be armed with a weapon*: Seven studies assessed this
20 factor, four of which used multivariate analysis to examine the data. Four of these
21 multivariate studies focussed on armed subjects, and one examined the *belief* that a
22 subject was armed. Of the four multivariate studies that focussed on armed subjects,
23 three found an association between armed subjects and TASER use. However, it must
24 be noted that two of these studies utilised the same dataset – so cannot wholly be
25 considered as distinct studies.
26
27
28
29
30
31
32
33
34
35
36 f) *Age*: Six studies assessed this factor, four of which were multivariate studies. Whilst
37 three of the four multivariate studies found no association between TASER use and
38 subject age, the remaining study found that subjects under 18 years of age were less
39 likely to have TASER used against them than subjects that were 18 years old or more.
40
41
42
43

44 **Global Factor Theme Three: Officer factors**

45
46
47 This global theme consisted of the following five factor subthemes which are examined in
48 turn below: (a) Ethnicity; (b) Role; (c) Length of Service; (d) Gender; and (e) Age.
49

- 50
51 a) *Ethnicity*: Six studies assessed this factor, all of which used inferential statistics to
52 explore the data. Five of these studies found an association between officer ethnicity
53 and TAESR use, and only one did not. The direction of these associations, however,
54 were far from consistent. Some studies found that TASER was less likely to be used
55
56
57
58
59
60

1
2
3 by officers of specific ethnicities (e.g., Black officers), whilst others found that non-
4
5 White officers were more likely to be involved in a TASER incident.
6
7

- 8 b) *Role*: Six studies examined this factor; five of which used inferential statistics to
9
10 examine the data. All but one of the quantitative studies that used inferential statistics
11
12 found an association between subject officer role and TASER use; with TASER use
13
14 being more likely for some roles (e.g., firearms officers, patrol officer), and less likely
15
16 for others (e.g., Response).
17
18
- 19 c) *Length of Service*: Seven studies examined this factor; six of which used inferential
20
21 statistics to examine the data. The majority of these studies found an association
22
23 between an officer's length of service and TASER use. The direction of this
24
25 relationship, however, was less clear. Some studies indicated that officer with longer
26
27 lengths of service were more likely to use TASER, whilst another indicated that those
28
29 with shorter tenures were more likely to be 'high-frequency' TASER users. These
30
31 results dovetail with those from the qualitative study which identified 'rookie' officers
32
33 as **being** utilising TASER more often.
34
35
36
37
- 38 d) *Gender*: Seven quantitative studies assessed this factor, all of which used inferential
39
40 statistics to examine the data. Five of these studies found no association between
41
42 officer gender and TASER, and the remaining two found that male officers were more
43
44 likely to use TASER.
45
46
- 47 e) *Age*: Four studies assessed this factor, all of which used inferential statistics to
48
49 examine the data. Four of these studies found an association between age and TASER
50
51 use, whilst one found no such association.
52
53

55

56 Discussion 57 58 59 60

1
2
3 This review sought to explore the currently available evidence regarding the factors
4 that impact an officer's decision to use TASER within the PSEW, and, more specifically,
5 whether officer crewing levels affect TASER use. As such, the discussion will begin by
6 examining the factors that are likely to be associated with, or effect the decision to use
7 TASER, before moving on to discuss the evidence relating to crewing levels and concluding
8 by presenting implications for current practice and future research.
9
10
11
12
13
14
15

16 17 **What factors are known to be associated with, or effect the decision to use, TASER?** 18

19 Analysis of the data extracted from the 20 studies included in this review examined
20 30 different variables (or factor sub-themes), all of which fell into the one of the following
21 three global factor themes: Situational, contextual and interpersonal elements, Subject
22 characteristics, and Officer factors. Of these 30, only nine were consistently found to be
23 significantly associated with TASER use across a number of studies; four of which were
24 related to the situation, context or interactional elements of the incident (i.e., incident
25 location, local policies, level of subject resistance/compliance, and the number of
26 subjects/bystanders), two of which were related to the characteristics of the TASER subject
27 (i.e., gender and perceived mental health status) and the remaining three were related to
28 officer factors (i.e., officer ethnicity, role, and length of service).
29
30
31
32
33
34
35
36
37
38
39
40
41

42 However, it must be noted, that even within these factor sub-themes the direction of
43 the association was not always clear. Whilst the evidence seems to suggest that TASER use
44 predominantly reflects local policy, that TASER subjects are more likely to be male than
45 female, and a subject is more likely to be involved in a TASER incident if they are perceived
46 as having mental health difficulties; the relationships between TASER use and the number of
47 bystanders, a subject's level of resistance/compliance, and the officer factors all appear to be
48 less clear.

59
60

Nonetheless, it is plausible that there is a common underlaying between several of these sub-themes relating to threat. Hine et al. (2018), for example, found that their participants overtly considered female subjects to be less threatening, and consequently did not feel as much force was necessary, whilst Quinton et al. (2020) found that subjects were more likely to have TASER used against them if they were perceived as mentally ‘disabled’ or if mental health was otherwise listed as an impact factor.

Given that over a third of the public think, incorrectly, that people with mental health problems are likely to be violent (Time to Change, 2015), perhaps it is not unreasonable to propose that officers consider these subjects as higher-risk due to assumptions about violent and unpredictable behaviour. However, according to the Home Office, protecting the subject was cited as a reason for using force in 43% of TASER incidents during the year ending March 2022 (Home Office, 2022a), indicating that officers may not just be worried about being the victim of violence themselves; but that they harbour serious concerns with regard to the risk that the subject poses to themselves.

Although the vast majority of variables examined across the studies included in this review appear to provide inconsistent, conflicting, or inadequate evidence to support their impact as a predictor of TASER use, discovering (or at least exploring) the reasons behind these discrepancies is a difficult, but necessary, task if we hope to better understand the nature and extent of TASER within the PSEW.

The first potential cause of such inconsistency is the differing international, national and local policing contexts in which these TASER incidents are taking place. For example, officers within different roles, units, regions, and countries will have varying levels of contact with the public, varying types of equipment, as well as differing access to TASER and the requisite training. Consequently, the opportunity and necessity to use TASER will vary depending on the officer, their role, and the wider context at hand.

1
2
3 In addition, Quinton et al. (2020) was the only study to explicitly control for access to
4 TASER at the incident level (i.e. whether an officer had access to TASER during the incident
5 where force was required). Access to TASER would, naturally, have a considerable influence
6 on an officers' opportunity (rather than decision) to use TASER, and given that there could
7 be any number of extraneous variables associated with TASER availability, failure to control
8 for this could provide a source of systematic bias in the data. For example, although Brandl
9 and Stroshine (2017) found a significant relationship between crewing and the use of
10 TASER, with the presence of more officers resulting in an increased likelihood of TASER
11 being used, this could be due to opportunity, rather than crewing, as it could be that the
12 likelihood of a *TASER carrying officer* being present increases with the number of officers in
13 attendance.
14
15
16
17
18
19
20
21
22
23
24
25
26
27

28 Another potential source of the conflicting results of this review is the inconsistent
29 way in which the variables were measured across studies. A good example of this is the way
30 in which a subject's level of resistance was measured. Although resistance was included in
31 two thirds of the review sample, operationalisation ranged from a single binary question
32 (Delone & Thompson, 2009) to response scales which listed three or four differing levels of
33 resistance (Brandl & Stroshine, 2017; Dymond, 2018). Pronounced differences in variable
34 measurements like these are likely to render any direct comparisons across studies
35 meaningless, as the variables cannot be compared like for like.
36
37
38
39
40
41
42
43
44
45
46

47 Another potential source of inconsistency is the method by which the data were
48 treated in preparation for the multivariate analyses. The majority of multivariate analyses
49 included in this review artificially dichotomised variables. For example, TASER was often
50 only examined as 'used' or 'not used,' with the reference category as being 'other use of
51 force,' or another specific type of force (e.g. OCS). However, conflating use of force options
52 into binary categories in this way may well obscure more subtle differences between similar
53
54
55
56
57
58
59
60

1
2
3 use of force options, as well as providing a limited scope in which the wider context of
4
5 TASER use cannot be examined. For example, it may be that crewing does not impact the
6
7 use of TASER when compared to all other types of force combined (including use of force at
8
9 the polar ends of a spectrum such as verbal commands and firearms), but it may influence an
10
11 officer's selection between uses of force that are more closely situated along the spectrum of
12
13 force, such as baton or OCS. This relationship might be masked if all non-TASER force is
14
15 aggregated into a single binary outcome.
16
17
18

19
20 Although this level of inconsistency across study findings is not ideal, it may not be
21
22 that unusual. The outcome of this review appears to be similar to that of a review in 2010 by
23
24 Klahm and Tillyer, which focussed on the wider issue of use of force as a whole and found
25
26 that few variables examined across the studies included in the review were highly influential
27
28 in the decision to use force, and many variables were found to have mixed or poor
29
30 relationships with use of force. Interestingly, they also concluded that male suspects, those
31
32 who were intoxicated, offered resistance, or were arrested during their encounter with police
33
34 were much more likely to experience police force. This perhaps indicates that TASER use
35
36 may follow the broader patterns seen within the wider use of force continuum.
37
38
39

40
41 Regardless of the potentially confounding issues listed above, another limitation that
42
43 needs to be addressed is the lack of any psychological or biological approaches to the
44
45 exploration of TASER use. Given that decision-making is a complex process that relies on a
46
47 myriad of factors, it is important to consider what Dror (2007) refers to as internal factors,
48
49 which includes (but is not restricted to) an officer's beliefs, values, prior learning, their
50
51 previous experiences and affect, cognitive ability, and the availability of their cognitive
52
53 resources (e.g. working memory). Only these factors can account for why individuals facing
54
55 the same decision, within the same context, often differs in their final choices. Indeed,
56
57
58
59
60

1
2
3 Dymond (2016) went so far as to say “*The use of Taser cannot be understood without an*
4 *emphasis on the decision making of the officers charged with using the weapon,*” (p. 187).
5
6

7 **Do crewing levels affect the frequency and type of TASER use by police officers?**

8
9
10 Although it could be argued that the overall results indicated that crewing levels could
11 potentially impact on an officer’s decision to use TASER, the evidence was fairly thin. Even
12 though seven out of the 20 studies explored crewing levels as part of their analyses, two of
13 these (DeLone & Thompson, 2009; White & Ready, 2007) were purely descriptive in nature
14 and, as such, could not be used to explore any potential relationship between crewing and
15 TASER use by police officers, and one was qualitative (Hine et al., 2018).
16
17
18
19
20
21
22
23

24 The remaining four studies used multivariate inferential analyses to explore the
25 impact of crewing on the use of TASER, but yielded conflicting results; with two finding a
26 significant relationship between crewing and TASER use (Brandl & Stroshine, 2017;
27 Quinton et al., 2020), and two finding no significant associations between the two variables
28 (Dymond, 2016, 2018).
29
30
31
32
33
34

35 It is possible, that the studies by Dymond (2016, 2018) found no statistically
36 significant relationships between the number of officers and the use of TASER due to their
37 sample. Although their policing population was taken from England and Wales, both papers
38 used the same sample which came from a single, predominantly rural, police force. This level
39 of specificity of the sample could have introduced a systematic bias into the analyses as
40 policing environments across England and Wales can be very different. These differences can
41 be especially pronounced between rural and urban environments, for example adults in urban
42 areas are more likely to be victims of violent crime than those in rural areas (Office for
43 National Statistics, 2019). As such, officers in more metropolitan areas may consider being
44 single-crewed as higher-risk than their rural counterparts, have better access to TASER, and
45 subsequently may be both more able, and willing, to use TASER.
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 These limitations, however, were somewhat addressed in the more recent British
4 study by Quinton et al. (2020). A similar approach to that of Dymond (2016, 2018) was used,
5 but Quinton et al. (2020) expanded their sample to include use of force data from 16 different
6 Police Forces across England and Wales, including some with more metropolitan
7 environments (e.g. Greater Manchester Police). Interestingly, Quinton et al.'s (2020) results
8 in relation to officer crewing differed from that of Dymond (2016, 2018); with officers that
9 were alone during a use of force incident being significantly more likely to discharge a
10 TASER than their colleagues that were accompanied by another officer (who did not use
11 force). Whilst these conflicting results may be, at least in part, due to the differing samples,
12 they could also be due to the different way that data were treated during analysis. For
13 example, in Dymond (2016, 2018) the analyses compared TASER use between incidents
14 where there was a single officer present, where there were two officers present, and when
15 there were more than two officers present. Quinton et al. (2020) however, compared the
16 TASER use between incidents where an officer was single-crewed at the time force was used
17 with those where officers were crewed with another officer *who did not use force*.

18
19 Given the conflicting results of the studies that examined the impact of crewing on
20 TASER use, the evidence regarding a possible association between crewing levels and
21 TASER must be considered, overall, to be a factor of uncertain influence; with the extent and
22 expression of any potential relationship, as well as any underlying drivers, remaining unclear.

23 24 25 **Implications for practice and policy**

26
27 For police legitimacy to be protected, all use of force needs to be used as sparingly
28 and appropriately as possible; cases of unnecessary, disproportionate, or unreasonable force
29 can put a strain on the relationship between the police and public. As such, any potentially
30 disproportionate use of TASER on vulnerable groups (such as those with mental health
31 conditions) should be of considerable concern to policy makers, the public, and the police
32
33

1
2
3 service alike. It is perhaps unsurprising then, that the role of the police and, more specifically
4 their use of TASER, within mental health emergencies is a hotly debated topic. Many health
5 professionals have raised concerns around the appropriateness of use of TASER and the
6 potential for creating additional trauma to those who are already in distress (Little, Hogbin &
7 Burt, 2013; O'Brien, & McKenna, 2007; O'Brien & Thom, 2014).
8
9

10
11
12
13
14
15 Although responding to mental health emergencies is not a new role for the PSEW, it
16 is one that has become more frequent as officers are increasingly expected to absorb the work
17 of other partner agencies (Betts & Farmer, 2019; Elliott-Davies et al., 2016; Elliott-Davies,
18 2019). However, it is not just TASER that appears to be used disproportionately against
19 vulnerable groups such as those with mental ill health, but the overall use of force has been
20 considered to be similarly concerning. According to the Independent Commission on Mental
21 Health and Policing (Adebowale, 2013), there have been recurrent failings in regard to
22 effective communication between police officers in the Metropolitan Police Service (MPS)
23 and people with mental ill health and vulnerabilities – and infers that this may be a factor in
24 the disproportionate use of force against this population. Moreover, the report suggests that
25 Personal Safety Training should be amended to specifically deal with the issue of TASER in
26 the context of mental health. However, evidence on whether or not this has been borne out in
27 practice is not publicly forthcoming, and more recent reports suggest that although additional
28 mental health and communication training for officers is required (HMICFRS, 2017),
29 investment in such training is currently inconsistent (Betts & Farmer, 2019; His Majesty's
30 Inspectorate of Constabulary and Fire & Rescue Services, 2018). Moreover, a recent national
31 review by HMICFRS (2018) indicates that funding cuts across the public services have left
32 the police to manage mental health crises in the community more often than they should, and
33 that although some police forces are investing in mental health training, the quality and
34 accessibility is, overall, quite variable.
35
36
37
38
39
40

44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Perhaps then, one policy recommendation would be to conduct an investigative
4 review into whether the recommendations from the Independent Commission on Mental
5 Health and Policing in 2013 (Adebowale, 2013) have been implemented within the
6 Metropolitan Police Service; and whether they perhaps also need to be implemented in other
7 forces.
8
9

10
11
12
13
14 Conversely, it is also worth policy makers noting that *avoiding* the use of TASER
15 when the appropriate circumstances arise may also be problematic as TASER use has been
16 found to reduce the odds of officers being assaulted (Quinton et al., 2020), and the vast
17 majority of TASER uses in England and Wales are non-discharge uses (i.e. where the
18 TASER is not fired at a subject; Home Office, 2022b)
19
20
21
22
23
24
25

26 Finally, due to the disproportionate use of TASER against the Black community
27 within the UK and the recent commencement of the independent review into this
28 disproportionality (Home Office, 2020; IOPC, 2020; National Police Chiefs' Council, 2020),
29 it would be remiss if subject ethnicity were not mentioned here. Although the results of the
30 eight multivariate studies that examined subject ethnicity during their analyses were
31 divergent, given social and contextual differences between countries, it is important to focus
32 on the results of those that used data from England and Wales (Dymond, 2016, 2018;
33 Quinton et al., 2020). Whilst Dymond (2016, 2018) found no associations between subject
34 ethnicity and TASER use, this may have been due to the predominantly rural force area being
35 examined. Data on regional ethnic diversity published by the UK government not only
36 indicates that Black ethnic groups are more likely to live in urban areas than their White
37 counterparts, but that only 2% of individuals from Black ethnic groups live in rural locations
38 (UK Government, 2018). Indeed, when Quinton et al. (2020) conducted similar data analyses
39 on comparable data from a wider range of UK police forces, they found that TASER was
40 more likely to be drawn against Black than White subjects during use of force incidents.
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 However, they also found that TASER was *less* likely to be used against members of the
4
5 Asian and Asian British communities; indicating that the relationship between TASER use
6
7 and ethnicity is perhaps more complex than the research has accounted for thus far, and that
8
9 there continues to be an urgent need for additional, more detailed data to be recorded and
10
11 published publicly.
12
13

14 **Implications for research**

15
16 Policing policy should be based on evidence and, as such, it is important to fully
17
18 understand the nature and extent of TASER use. Only then can training protocols be tailored
19
20 to the appropriate use of TASER, and deliver policy that is formulated to instruct officers as
21
22 to appropriate use.
23
24

25
26 The results of this review not only indicate that the understanding of the factors
27
28 associated with TASER use and the underlying mechanisms driving them could be improved,
29
30 but also the way in which data relating to these factors are collected, measured, and analysed.
31
32 In particular, it would be useful for future research to work towards a more constant
33
34 measurement framework so that data collection and analysis methods relating to TASER use
35
36 are more standardised, comparable and, ultimately, more useful.
37
38

39
40 The existing studies also appear to neglect the role of discretionary decision-making
41
42 of individual officers, and the internal factors of individual officers that may influence their
43
44 decision outcomes. As such, it would be beneficial for additional future research to
45
46 concentrate on officers' thoughts, feelings, and behaviours in addition to their socio-
47
48 occupational demographic characteristics.
49
50

51
52 Finally, future research may also benefit from taking a qualitative approach to
53
54 examine why and how officers use TASER, as this may provide a richer understanding of the
55
56 causal mechanisms for the officers' choices – supplementing the qualitative approaches
57
58 utilised by the majority of research thus far.
59

Table I: Key Concepts and Related Search Terms

Key concepts	Search terms
1 Crewing level	Single-crew*, “Lone working”, “Working alone”, “Single crew”, “Single crewing”, “Single patrol”, “Single-patrol”, “Crewing level”, “Crewing”, “Crewing-level”, “Crew*”.
2 Decision	Decision, Choice, Choos*, Decid*, Elect, Opt, “Decision making”
3 TASER	TASER, “Less-lethal-force”, “Less-lethal force”, “Less lethal force”, “Non-lethal-force”, “Non-lethal force”, “Non lethal force”, “Non-lethal-alternatives”, “Non-lethal alternatives”, “Non lethal alternatives”, “Conducted electrical weapon”, “Conducted energy device”, “Conductive electrical weapon”, “Conductive energy device” ¹
4 Police	Polic*, Officer*, Constable*.

¹ Please note, the last two search terms listed under key concept three (i.e., TASER) were identified and included after the search protocol was developed and submitted to PROSPERO.

Table II: Interrater Reliability Scores

Record	Kappa	95% CI	Agreement level (Landis & Koch, 1977).
Dymond (2018)	0.59 (p<.000)	(0.331, 0.857)	Moderate
White and Ready (2007)	0.56 (p<.000)	(0.619, 1.000)	Moderate
Hine et al., (2018)	0.62 (p<.000)	(0.190, 0.928)	Moderate

Table III – Final Review Sample Data Summary

Reference	Country	Overall design	Overall quality assessment score*	Data collection method and sample size	Key outcome variables of interest	Key emergent or related variables of interest ¹
1 Bishopp, Klinger and Morris (2015)	USA	Quantitative: Complex correlational design	Correlational Studies <i>EV Score:</i> + <i>IV Score:</i> +	Data were collected from official use of force forms/data collection processes. 4,400 observations across 275 officers (monthly TASER use frequency for each officer).	<ul style="list-style-type: none"> • Frequency of TASER use 	<ul style="list-style-type: none"> • Local TASER and use of force policies • Officer ethnicity • Officer gender
2 Boehme, Martin & Kaminski (2021)	USA	Mixed methods with two designs. <i>Design 1:</i> Descriptive <i>Design 2:</i> Complex correlational design	Quantitative Studies <i>EV Score:</i> + <i>IV Score:</i> +	<i>Design 1:</i> Data were collected via a survey of local police agencies. 74 survey responses out of 169 eligible agencies were received (44% response rate). <i>Design 2:</i> Data were collected from official use of	<ul style="list-style-type: none"> • Frequency of TASER use • Type of TASER use (e.g., discharge vs non-discharge) 	<ul style="list-style-type: none"> • Local TASER and use of force policies

¹ Only outcome and predictor variables included in the final evaluation are presented in this table

Reference	Country	Overall design	Overall quality assessment score*	Data collection method and sample size	Key outcome variables of interest	Key emergent or related variables of interest ¹
				force forms/data collection processes. 60-62 observations (monthly TASER use frequency for the local agency).		
3	Brandl and Stroshine (2017)	USA	Quantitative: Complex correlational design	Correlational Studies <i>EV Score:</i> + <i>IV Score:</i> +	Data were collected from official use of force forms/data collection processes. Use of force forms between 2010 and 2011 where oleoresin capsicum spray (OCS), TASER or both, were used. In total, 528 cases were included.	<ul style="list-style-type: none"> • Frequency of TASER use • Sequential position of TASER use during incident • Number of officers present • Number of subjects and/or bystanders • Level of subject resistance/compliance • Subject ethnicity • Subject gender • Subject age • Perceived mental illness and mental or emotional 'disturbance' of subject • Perceived intoxication of subject • Subject armed, or believed to be armed with a weapon
4	Crow and Adrion (2011)	USA	Quantitative: Complex correlational design	Correlational Studies <i>EV Score:</i> + <i>IV Score:</i> +	Data were collected from official use of force forms/data collection processes. In total, 461 cases were included.	<ul style="list-style-type: none"> • Frequency of TASER use • Type of call/offence/incident • Local TASER and use of force policies • Time of day and/or lighting • Level of subject resistance/compliance

20 White and Ready (2007)	USA	Quantitative: Descriptive	Quantitative Studies EV Score: ++ IV Score: +	Data were collected from official use of force forms/data collection processes. In total, 243 cases were included.	<ul style="list-style-type: none"> • Frequency of TASER use 	<ul style="list-style-type: none"> • Number of officers present • Local TASER and use of force policies • Location • Subject age • Perceived mental illness and mental or emotional ‘disturbance’ of subject • Perceived intoxication of subject • Subject armed, or believed to be armed with a weapon • Officer role

* Each quantitative study is awarded an overall study quality grading for internal validity (IV) and a separate one for external validity (EV), and qualitative studies receive a single overall grade using the groups below:
 ++ All or most of the quality assessment checklist criteria have been fulfilled, where they have not been fulfilled the conclusions are very unlikely to alter.
 + Some of the quality assessment checklist criteria have been fulfilled, where they have not been fulfilled, or not adequately described, the conclusions are unlikely to alter.
 – Few or no quality assessment checklist criteria have been fulfilled and the conclusions are likely or very likely to alter.

Table IV: Theme Table for Factors Effecting TASER Use

Global factor theme	Factor subthemes	Overall factor evaluation	Summary of evidence ¹
1. Situational, contextual, and interactional elements	a) Level of subject resistance/compliance	Potentially influencing factor	<p>15 Studies in total</p> <p>2 x Descriptive Studies (DeLone & Thompson, 2009; Mesloh et al., 2005)</p> <p>3 x Qualitative Studies (Escalante, 2020; Hine et al., 2018; Sierra- Arévalo, 2019)</p> <p>2 x Bivariate Studies 2 x <i>studies found association(s)</i> (Ready & White, 2011; Sousa et al., 2010)</p> <p>8 x Multivariate Studies 1 x <i>study found no association(s)</i> (Brandl & Stroshine, 2017) 7 x <i>studies found association(s)</i> (Crow & Adrion, 2011; Dymond, 2016, 2018; Gau et al., 2010; Kuzik, 2019; Lin & Jones, 2010; Quinton et al., 2020)</p>
	b) Local TASER and use of force policies	Potentially influencing factor	<p>8 Studies in total</p> <p>1 x Descriptive Study (White & Ready, 2007)</p> <p>1 x Bivariate study 1 x <i>study found no association(s)</i></p>

¹ Where studies have utilised a number of relevant analyses, they are listed under the most robust type of analysis included in their reporting. For example, where a study has reported relevant descriptive statistics as well as the results from a pertinent bivariate analysis, they will be listed under 'Bivariate Study' only.
